Dedication

To my parents, Lawrence and Irma Shapiro,
For your years of endless guidance, support, and love –
thank you

To my beloved niece and goddaughter, Phoebe Maras
Follow your dreams and make them a reality

Preface

National and international security concerns have considerably evolved. Globalization has triggered growing and exponential threats that challenge the security and stability of countries by transcending traditional borders and having a transnational impact. To understand these security threats and the ways to counter them, a multidisciplinary approach to their examination is required. This encyclopedia was written to fill the void by comprehensively covering various facets of security through a multidisciplinary lens of criminology, criminal justice, sociology, psychology, law, police studies, political science, history, risk, computer science, management, and public policy and administration. Particularly, this encyclopedia provides students, academics, and practitioners in a wide range of fields with comprehensive and contemporary information on security. The topics range from security threats (e.g., cybercrime, terrorism, shoplifting, and fraud) to both applications on the job and coordination between public and private sectors in handling security and emergency situations nationally and internationally. The chapters cover security concepts, methods, functions, theories, organizations, and technology; the history and current state of the discipline; security measures (i.e., physical security, personnel security, and cybersecurity); critical infrastructure protection; emergency management; and public-private partnerships. The encyclopedia will serve as a resource allowing readers to learn best practices in security; understand weaknesses in current techniques; develop risk assessment skills; predict vulnerability in a range of businesses and critical infrastructure sectors (e.g., healthcare, energy, water, dams, financial, commercial, and government facilities, communications, and information technology sectors, to name a few); and implement mechanisms for managing natural and human-made disasters.

Acknowledgments

We would like to extend our warm thanks to Ruth Lefèvre at Springer for her direction and assistance during the development and production of this encyclopedia.

Our gratitude is extended to all of the authors for their contributions and reviewers (listed below) for their valuable insight to ensure that the encyclopedia contained comprehensive, excellent material.

Reviewers

Alex Alexandrou, Chelsea Binns, Robert Matthiessen, Robert D. McCrie, Susan Pickman, Robert Till, Lucia Velotti, and Hung-Lung Wei

List of Topics

Airport Security: Incidents That Changed Procedures
Airport Security: Procedures in Secured Areas for TSA and Private Security
American Society for Industrial Security (ASIS)
Arrest
Big Data
Biometrics
Border Security
Bribery
Bus Security
Business Continuity Plan
Celebrity Protection

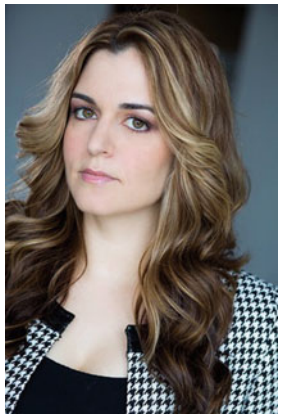
About the Editors

Dr. Lauren R. Shapiro is an Associate Professor in the Department of Security, Fire, and Emergency Management at John Jay College in New York. Her Ph.D. is in Developmental Psychology from Rutgers University, and she also has an M.S. in Criminal Justice from Indiana University, an M.S. in Experimental Psychology from Ohio University, and a dual B.A. in Psychology and in Early Childhood Education from the University of Buffalo. Dr. Shapiro was a Postdoctoral Research Fellow at the Carolina Consortium on Human Development at the University of North Carolina, Chapel Hill. She served as an Extern with the Honorable Ralph Erickson in the US District Court of North Dakota, Fargo, and as an Intern with the Fargo Police Department. Dr. Shapiro has certificates from the Royal Canadian Mounted Police in First Responder Terrorism Awareness (core program) and from the City of Fargo ND in Child Custody Investigator. She teaches professional training workshops and certificate courses for justice and security professionals. Dr. Shapiro consults with psychologists, attorneys, and officials in the police, sheriff, and district attorney departments and has been interviewed about her work by television and newspaper journalists. She is the co-author of *Multidisciplinary Investigation of Child Maltreatment* (Jones and Bartlett, 2016) and author of *Cyberpredators and Their Prey* (CRC Press), which should be available next year. Her research, which focuses on various issues in physical security, border security, private investigation, cyber security, and school safety and security, has been presented at national and international conferences and published in journals and books.



Dr. Marie-Helen (Maria) Maras is an Associate Professor at the Department of Security, Fire, and Emergency Management at John Jay College of Criminal Justice. She is also part of the faculty of the M.S. program in Digital Forensics and Cybersecurity at John Jay College of Criminal Justice and the Ph.D. program in Criminal Justice at the CUNY Graduate Center. Dr. Maras has a DPhil. in Law and an MPhil in Criminology and Criminal Justice from the University of Oxford. In addition, she holds a graduate degree in Industrial and Organizational Psychology from the University of New Haven and undergraduate degrees in Computer and Information Science and Psychology from UMUC. She is the author of *Cybercriminology* (Oxford University Press, 2016); *Computer Forensics: Cybercriminals, Laws, and Evidence* (now in its second edition; Jones and Bartlett, 2014); *Counterterrorism* (Jones and Bartlett, 2012); *CRC Press Terrorism Reader* (CRC Press, 2013); and *Transnational Security* (CRC Press, 2014), among other publications. Prior to her academic post, she served in the US Navy for approximately seven years, gaining significant experience in security and law enforcement from her posts as a Navy Law Enforcement Specialist and Command Investigator. During the early stages of her military career, she worked as an Electronics and Calibration Technician.

Airport Security: Incidents That Changed Procedures

Heather A. Panter
Centre for Advanced Policing Studies,
Liverpool John Moores University,
Liverpool, UK

Keywords
Terrorism · Skyjackings · Hijackings · Airplane bombings · Airport security

Definition

A security incident that changed security procedures is defined by the involvement of the following essential components: hijacking, skyjacking for ransom, attempted bombings/bombing incidents on planes, and/or attacks on airport structures themselves. In respect to hijacking, a hijacking is the seizure of a plane's control by force or threat of force. Skyjacking is the kidnapping of passengers of an airplane by threats of force for ransom whether monetary or political. Besides the historical analysis of these crimes and forms of terrorist activities targeted at commercial aviation, this entry describes how specific security incidents influenced airport security procedures.

Introduction

Modern aviation is favored as a target for attacks because of its vulnerabilities and human, psychological, and economic repercussions. Notably, planes are highly visible targets that are readily associated with specific nations, and a successful attack generates a large number of causalities with a high level of press coverage. Further, commercial aircraft are often regarded as "symbols of Western technological prowess" (Chow et al. 2005, p. 3). Hence why hijackers and bombers alike often target them. Proactively, security tactics have evolved to address specific techniques used during attacks. Often these changes are a direct result of specific incidents that commercial aviation has had to face. Examining timelines of attacks upon commercial aviation, there are distinct tactical phases both pre-9/11 and post-9/11. With each distinct phase, the tactics of attackers caused procedural changes in commercial airport security.

Pre-9/11

Nitroglycerin Carry-On Luggage Bombings (1933–1960s)

The first commercial plane bombing occurred on October 10, 1933, on a United Airlines Boeing

© Springer Nature Switzerland AG 2021

https://doi.org/10.1007/978-3-319-70488-3

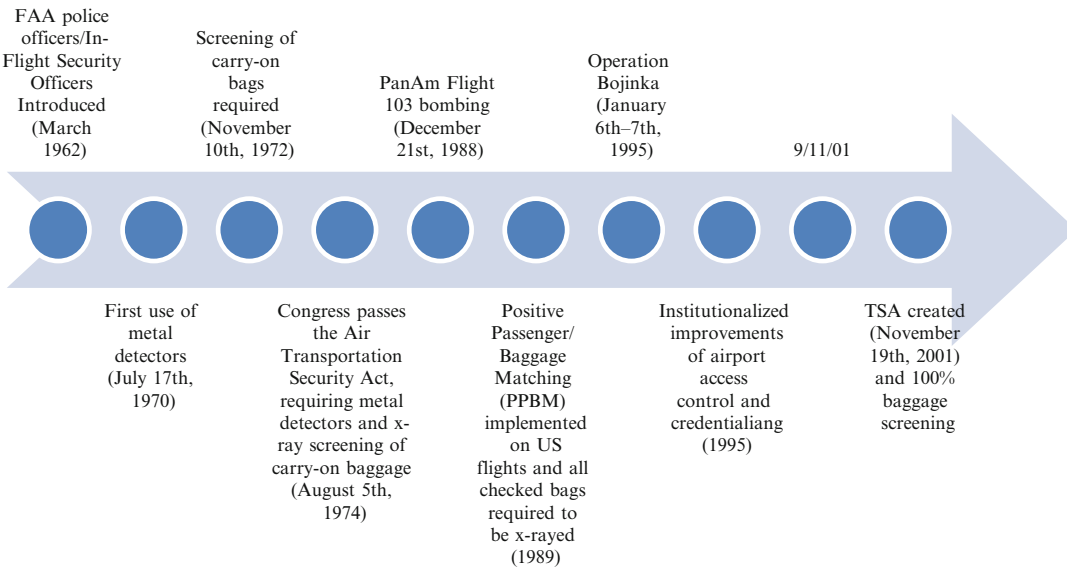
247 (Van der Linden and Seely 2011). The case remains unsolved today, but it is suspected that the nitroglycerin bomb was a result of a Chicago gang murder plot (Van der Linden and Seely 2011). While this incident did not lead to changes in security procedures, it was a litmus test for how future bombings would be carried out on commercial airlines (refer to Fig. 1), namely, packing dynamite in suitcases and carrying it aboard via passenger luggage [see Canadian Pacific Air Lines (1949), Kashmir Princess (1955), United Airlines Flight 629 (1955), National Airlines Flight 967 (1959), and National Airlines Flight 2511 (1960)].

Creation of Air Marshals (1960s–Current)

In 1961, Antuilo Ramierez Ortiz used a gun to force the flight crew of a National Airlines jet to divert to Cuba and thus became the first US hijacker (Department of State 2006). This incident, along with the hijacking epidemic occurring during the time, leads to the creation of the first air marshal program. In March 1962, in-flight security began with the US Federal Aviation Administration introduction of FAA Peace Officers who covertly traveled on planes to combat airline skyjackings (Elias 2009). These FAA Peace Officers, or known worldwide as In-Flight Security Officers (IFSOs), were the first people to provide armed security onboard commercial aircraft. Since their institution to commercial airliners, the FAA has handed security duties to the TSA. Internationally, covert in-flight surveillance has been in operation after FAA implementation [Australia (2001), Austria (1981), Canada (2002), India (1999), Ireland (1970s), Pakistan (1976), United Kingdom (2003), etc.].

"Golden Age" of Skyjacking and Passenger Screening (1970s–1980s)

By 1970, hijackings reached epidemic proportions with 118 incidents of unlawful aircraft seizures and 14 incidents of sabotage/armed attacks against commercial airlines (Price and Forrest 2016). Screening passengers and carry-on baggage started in the early 1970s as a way to deter hijackings that was regulated by airline industries themselves. This often led to subcontracted screenings by vendors with the lowest bid (Price and Forrest 2016). As such, screening companies had high turnover rates with staff often under-



FAA police officers/In-Flight Security Officers Introduced (March 1962)
First use of metal detectors (July 17th, 1970)
Screening of carry-on bags required (November 10th, 1972)
Congress passes the Air Transportation Security Act, requiring metal detectors and x-ray screening of carry-on baggage (August 5th, 1974)
PanAm Flight 103 bombing (December 21st, 1988)
Positive Passenger/ Baggage Matching (PPBM) implemented on US flights and all checked bags required to be x-rayed (1989)
Operation Bojinka (January 6th–7th, 1995)
Institutionalized improvements of airport access control and credentialiang (1995)
9/11/01
TSA created (November 19th, 2001) and 100% baggage screening

Airport Security: Incidents That Changed Procedures, Fig. 1 Pre-9/11 Security Reactive Measures Timeline

qualified (Price and Forrest 2016). This led to several airport security failures.

Notably, prior to the introduction of standardized regulations, passenger screening for guns and hand grenades (the most common tactics at the time) leads to a reduction of airline incidents, and thus, the evolution of security screening programs halted due to financial demands placed upon airliners combined with a reduction of hijackings. At the time, the financial cost of security screening often superseded any proactive security desires. So private airlines and airports, which were responsible for providing security, often relied upon minimal cost-effective measures that were reactive instead of effectively proactive.

Strategically during this time, airline acts of sabotage remanded consistent with either a bomb concealed in checked-in baggage, body-worn explosives, or body-worn handguns. Yet, criminal tactics changed, and airlines/airports had to reconsider their cost-prohibitive security attempts. On November 10, 1972, hijackers (Melvin Cale, Louis Moore, Henry D. Jackson, Jr.) threatened to fly Southern Airways Flight 49 into a nuclear reactor in Oak Ridge Tennessee (Department of State 2006). This was the first time when a plane was attempted to be used as a weapon. Strategically, this highlighted how the failure of adequate passenger screening could have a larger destructive impact financially, politically, and psychologically to airline acts of sabotage globally. This particular significant incident could be arguably be connected to the similar tactic used by 9/11 hijackers.

Shortly before takeoff from Birmingham, Alabama, Southern Airway Flight 49 hijackers produced handguns and hand grenades and took over the commercial flight with 34 people onboard demanding $10 million (Price and Forrest 2016). During the 30-hour hijacking, hijackers had the plane make multiple stops in the USA and Canada while threatening to fly into the High Flux Isotope Reactor at the Oak Ridge National Laboratory (Naftali 2009). During negotiations with the FBI, officials only managed to get between $2 and $2.5 million of ransom money while landed in Chattanooga, Tennessee (Naftali 2009). If successful in crashing the plane into the nuclear reactor, the nuclear fallout would have been arguably as devastating as Chernobyl. The hijackers then set course for Havana, Cuba, but Cuban leader Fidel Castro refused their admittance into the country; therefore, the plane was flown to Orlando, Florida, to refuel. The FBI shot out two of the four tires of the plane, and the hijackers shot the copilot while ordering the plane to take off again to Cuba (Naftali 2009). Once landed in Cuba, the hijackers were removed via gunpoint by Cuban authorities. This specific incident, combined with other hijackings, leads to an emergency ruling by the US Federal Aviation Administration to mandate screening of all passengers and inspect carry-on luggage (Yoo and Choi 2006). With this incident, along with the increasing international political unrest, the FAA recognized the strategic need to expand and improve security screening despite previous cost operative tactics.

FAA Introduction of Explosive Detection Canine Teams (1972)

When TWA Flight 7 departed New York's JFK airport, the airline was notified that a bomb was hidden onboard. Since, bomb threats were so common, it took 10–15 min to determine if the threat was a hoax (Witkin 1972). The flight was redirected back to JFK and was promptly evaluated. During the subsequent plane search, a bomb-detecting K-9 discovered a device in the jetliner's cockpit minutes before it was set to detonate (Witkin 1972). The device was hidden in a black suitcase and was constructed of C-4 (plastic military explosive), which went undetected by metal detectors used during preflight screening. Notably, the FAA recognized that the current usage of x-ray and metal detector technologies was insufficient in detecting plastic explosives, and they sought more effective detection methods. As such, this specific incident led to the creation of the FAA Explosive Detection Canine Team Program. Notably, K-9 bomb detectors are faster, more versatile, reliable, and more cost-effective than conventional instrumental detection methods (see Furton and Myers 2001).

Deliberate Sabotage and IED Suitcase Bombings (1980–1990s)

Pan Am Flight 103

From the 1960 to 1970s, security focus changed from hijackings toward detecting deliberate sabotage in the 1980–1990s (Fobes et al. 1995). Notably, on December 21, 1988, a suitcase bomb on Pan Am Flight 103 killed 244 passengers, 15 crewmembers, and 11 residents on the ground in Lockerbie, Scotland (Elias 2009). Following a lengthy investigation, it was determined that two Libyan nationals (arrested in November 1991) with the assistance of Libyan intelligence officer Abdelbaset al-Megrahi (arrested in 2001) were identified as the bombing suspects. Libyan leader Muammar Gaddafi also accepted responsibility in 2003 and paid compensation to the victims despite his contradictory claim that he did not give the order to attack. Because of this incident, positive passenger/baggage matching (PPBM) became a regulatory responsibility in the USA for international flights (Elias 2009). Previously, baggage could be checked onto flights without a corresponding passenger. Further, US carriers at European and Middle Eastern airports required PPBM matched baggage to undergo x-ray and hand searches of all checked baggage after Pam Am Flight 103 bombing.

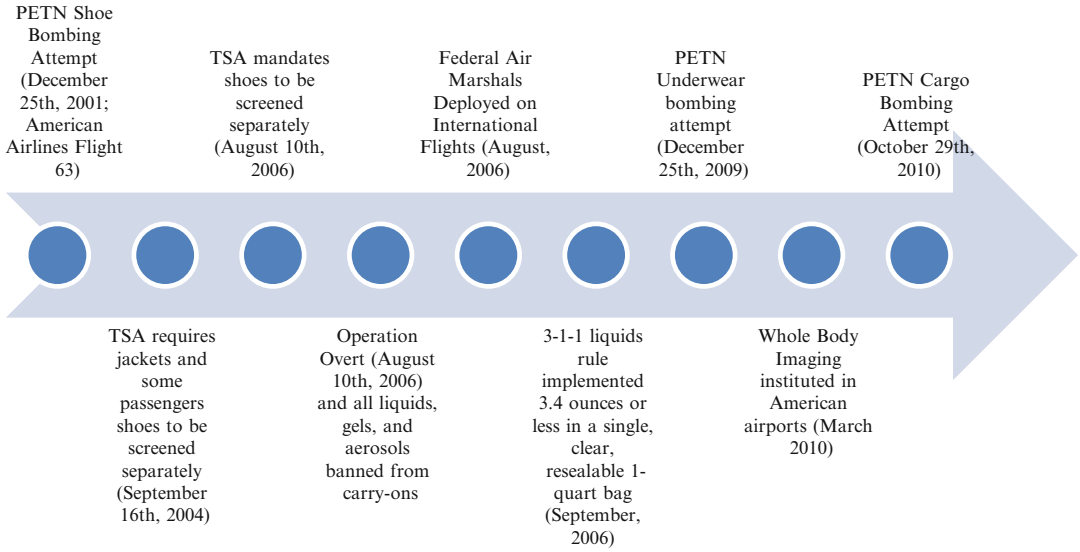
PSA Flight 1771

Strategically, bomber tactics changed from checked baggage bombs back to carry-on baggage devices. This was a direct result to the countermeasures that were instituted after Pam Am Flight 103. On January 6–7, 1995, Ramzi Yousef and two Al-Qaeda coconspirators were foiled in the bombing attempts of 12 US commercial airliners on international routes (Operation Bojinka). Yousef's Cell had planned to use liquid-based explosives that were undetectable by the screening technologies currently in use at airports (Price and Forrest 2016). Notably, had the bombing plot been successful, the death toll would have been one of the most devastating terrorist attacks upon commercial airlines. Because of this incident, development of additional policies and procedures, specifically airport access control and credentialing (i.e., badging and background checks), was instituted. Further, because of this failed mass-bombing incident, Khalid Sheikh Mohammed (considered to be the architect of the 9/11 attacks) decided to tactfully move away from explosives and to use airplanes themselves as weapons.

Post 9/11 Attacks (Person-Borne IEDs)

Prior to September 11, 2001, airport screening was provided by private agencies contracted through airlines or airports. On September 11, 2001, hijackers Khalid al-Mindhar, Nawaf al-Hazmi, and Salem al-Hazmi set off metal detectors during preflight screening. CCTV video of the footage showed that they had what appeared to be box cutters attached to their back pockets. Notably, box cutters and small knives were at the time allowed to be carried aboard aircraft. Using box cutters and suspected faux body bombs, four planes were hijacked (two crashed into the twin towers of the World Trade Center, one crashed into the Pentagon, and the fourth plane crashed into a field in southern Pennsylvania) which killed over 3,025 US citizens and other nationals. (The death count continues to increase from responders/volunteers who have contracted 9/11-related cancers, pulmonary diseases, mental health stress-related conditions, and other medical conditions. It is anticipated that more responders will die from these illnesses by the end of 2018 than those actually killed on 9/11 (Never Forget Project 2018).)

Two months after the September 11 attacks, US lawmakers made airport security a federal issue by standardizing pre-boarding screening procedures through the creation of the TSA (Transportation Security Agency). Part of this standardization of pre-boarding security processing leads to the banning of certain carry-on items and stricter screening that was continuous federally in the USA (refer to Fig. 2). Other changes included the restriction of non-ticketed individuals into secured passenger areas, fortified aircraft cockpits, TSA's Federal Flight Deck Officers Program (arming crewmembers), and 100% checked baggage screening.



PETN Shoe Bombing Attempt (December 25th, 2001; American Airlines Flight 63)
TSA requires jackets and some passengers shoes to be screened separately (September 16th, 2004)
TSA mandates shoes to be screened separately (August 10th, 2006)
Operation Overt (August 10th, 2006) and all liquids, gels, and aerosols banned from carry-ons
Federal Air Marshals Deployed on International Flights (August, 2006)
3-1-1 liquids rule implemented 3.4 ounces or less in a single, clear, resealable 1-quart bag (September, 2006)
PETN Underwear bombing attempt (December 25th, 2009)
Whole Body Imaging instituted in American airports (March 2010)
PETN Cargo Bombing Attempt (October 29th, 2010)

Airport Security: Incidents That Changed Procedures, Fig. 2 Post 9/11 Attacks (Rise in Aircraft Bombing Attempts with Person-Borne Explosives) Timeline

Internationally, following 9/11, Annex 17 was adopted by the International Civil Aviation Organization (ICAO) Council to address challenges posed to civil aviation (International Civil Aviation Organization 2011). This amendment included new provisions in airport security operations, international cooperation relating to threat information, national quality control, access control at airports, measures related to passengers and their cabin and hold baggage, in-flight security personnel and protection of the cockpit, code-sharing/collaborative arrangements, and management of response to acts of unlawful interference (International Civil Aviation Organization 2011).

PETN Christmas Day Shoe Bomber (2001)

Despite the security measures that were put into place by ICAO, suspects quickly responded by shifting to onboard suicide attacks with concealed person-borne IEDs (Improvised Explosive Device). On December 25, 2001, Al-Qaeda member Richard Reid wore shoes which contained undetected pentaerythritol tetranitrate (PETN) aboard a flight. Pentaerythritol tetranitrate (PETN) is a powerful explosive, which is part of the same chemical family as nitroglycerin and is rarely detectable with conventional "single beam" x-ray machines (see Wells and Bradley 2012). Manufactured as a white powder, it is often a component of plastic explosives like Semtex. It is relatively stable and used primarily as a high explosive. During American Airlines Flight 63, Reid unsuccessfully attempted to detonate the explosive while using triacetone triperoxide (TATP) as a detonator (Wells and Bradley 2012). With this unsuccessful attack, shoes were required to be screened separately, and suspects switched to camouflaging containers filled with liquid explosives.

Operation Overt (2006)

On August 2006, British authorities disclosed that they had interdicted planned attacks of ten transatlantic flights with liquid explosives carried in their hand luggage. MI5 conducted an investigation called Operation Overt where they broke into a flat being used by Ahmed Ali and hid cameras and microphones. Through their surveillance, MI5 determined that Ahmed Ali and Tanvir Hussain were constructing IED devices out of drink bottles. Both suspects experimented with introducing liquid explosives via a syringe into an empty soft drink bottle. The suspects also planned to use a disposable camera for IED parts

and hid an altered AA battery that would be a detonator in carry-on baggage. The disposable camera in question was intended to provide an electrical charge to the detonator that would be strapped to the bottle filled with liquid explosives. This leads to security measures that limited the amount of liquids, aerosols, and gels allowed in carry-on luggage (Wells and Bradley 2012). Further, this significant incident influenced the development and implementation of effective mass-screening technology that better detects explosive liquids (Wells and Bradley 2012). Notably, adjusted security measures restricted the quantity of liquids that people could take aboard aircraft, suspects altered the paradigm once more with the underwear bombing using a device with no metal components.

PETN Underwear Bomber (2009)

On December 25, 2009, an Al-Qaeda extremist (Umar Farouk Abdulmutallab) attempted to detonate an IED concealed in his underwear while aboard a flight from Amsterdam to Detroit (USA) (Bunker 2011). Inside Abdulmutallab's underwear was 80 g (2.8 oz.) of PETN (Bunker 2011). According to intelligence officials, Ibrahim al-Asiri, the chief bomb-maker for Al-Qaeda in the Arabian Peninsula (AQAP), created the device. This leads to the TSA introducing whole-body imaging to security screening procedures in March 2010. Further, laptops and tablets were required to be removed from hand baggage for better screening (see Wetter 2013), the implementation of enhanced pat-downs by TSA officials, and restrictions on cargo occurred due to this incident. Notably, suspects took advantage of metal detector weakness of their failure to detect organic materials comprising of liquid and plastic explosives (Sweet 2009), including TATP, C4/PE4, and PETN.

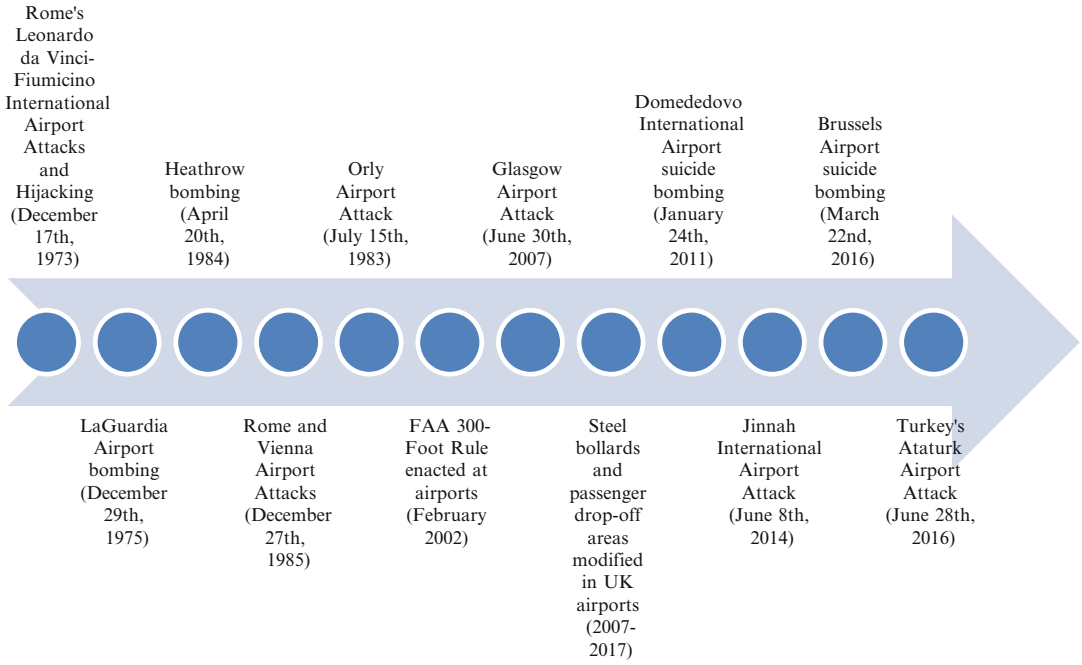
PETN Cargo Bombing Attempt (2010)

Both the raised concerns of a potential internal carrier bomber and the increase in security measures in response to the underwear bombing, AQAP decided to attack cargo aircraft with IEDs hidden in printer toner cartridges. On October 29, 2010, IEDs were found aboard separate cargo flights as a result of intelligence from Saudi Arabia's security chief (Bunker 2017). The IEDs were discovered at stopovers from Yemen at East Midlands (UK) and Dubai (UAE). Both devices where posted in Yemen with freight firms UPS and FedEx with shipping addresses to former locations of two synagogues in Chicago. Reports stated that the devices were meant to detonate midair over US cities (see Bunker 2017). Notably, Yemen does not have regularly scheduled cargo flights, and the suspects likely knew the IEDs would end up on passenger planes as over 50% of airfreight to the USA is transported in the cargo hold of passenger planes (see Rayner and Gardham 2018). The IEDs on both cargo planes were concealed in printer cartridges inside Hewlett-Packard HP desktop laser printers. The printers contained an electrical circuit connected to a mobile phone SIM card and the printer cartridge contained 14 oz. of PETN. Through the investigation of the incident, it was determined that Anwar al-Awlaki was responsible for the attempt with Ibrahim al-Asiri, the chief bomb-maker for AQAP, responsible for the construction of the device. Notably, Ibrahim al-Asiri's IED devices have been reported as being used in the 2009 Christmas Day bomb plot, the 2010 cargo bomb plot, and the May 8, 2012, terror plot.

Because of the PETN Christmas Day Shoe Bomber (2001), Operation Overt (2006), PETN Underwear Bomber (2009), and the PETN Cargo Bombing Attempt (2010), TSA deployed over 500 Advanced Imaging Technologies units, or whole-body imaging, to screen for both non-metallic and metallic threats. Additionally, TSA instituted "enhanced" secondary screening for passengers who decline WBI screening techniques. During this time, TSA implements the Secure Flight program which cross-checks passenger names against a watch list of known or suspected terrorists (see ► "Airport Security: Procedures in Secured Areas for TSA and Private Security").

Attacks on Airport Structures (1973–Current)

As a fundamental problem of aviation, security revolves around the best way to allocate scarce



Rome's Leonardo da Vinci-Fiumicino International Airport Attacks and Hijacking (December 17th, 1973)
Heathrow bombing (April 20th, 1984)
Orly Airport Attack (July 15th, 1983)
Glasgow Airport Attack (June 30th, 2007)
Domededovo International Airport suicide bombing (January 24th, 2011)
Brussels Airport suicide bombing (March 22nd, 2016)
LaGuardia Airport bombing (December 29th, 1975)
Rome and Vienna Airport Attacks (December 27th, 1985)
FAA 300-Foot Rule enacted at airports (February 2002)
Steel bollards and passenger drop-off areas modified in UK airports (2007-2017)
Jinnah International Airport Attack (June 8th, 2014)
Turkey's Ataturk Airport Attack (June 28th, 2016)

Airport Security: Incidents That Changed Procedures, Fig. 3 Airport attacks timeline

resources to reduce the probability of a successful attack, terrorism tactics shifted from the sky, which was being regulated with tighter security (see Fig. 2), to ground attacks. Strategically, with the introduction of passenger and baggage screening, terrorists adapted their approach to specifically attack airport infrastructures themselves (refer to Fig. 3). As airport infrastructures pose unique security vulnerabilities, they have become more attractive, easier, and cause significant financial impact. For example, Chow et al. (2005) theorized that the downing of an airliner via shoulder-fired missile would lead to an economic loss more than $15 million. Stewart and Mueller (2014) further theorized that airport infrastructure attacks (like those highlighted in Fig. 3) can cost over $30 billion in airline losses.

2007 Glasgow Airport Attack via Vehicle

On June 30, 2007, a terrorist used a Jeep Cherokee filled with propane canisters in a ramming attack, which resulted in a fire. Luckily, security bollards outside the entrance stopped the vehicle from entering the terminal (Price and Forrest 2016). Yet, when the vehicle failed to drive through the terminal, terrorist Bilal Abdullah threw petrol bombs from the passenger seat of the vehicle (Brocklehurst 2017). The other terrorist and driver, Kafeel Ahmed, was set alight during the fire and baggage handler John Smeaton kicked Ahmed in the groin subduing him while helping an injured victim (Brocklehurst 2017). For his actions, John Smeaton was awarded the Queen's Gallantry Medal and became a cult hero in Scotland. Notably, several other heroes that day (off-duty police, airport employees, passengers, and cab drivers) assisted in the thwarting of the attack. From a security perspective, new carports and drop-off and pick-up zones were installed which reduced the flow of vehicle traffic near the airport in an effort to deter future terminal attacks. Additionally, other UK airports either blocked off roads that approached terminal buildings or rerouted traffic while introducing more blockades policed by local forces.

Conclusion

As indicated in this entry, significant incidents, crimes, and forms of terrorism have affected and evolved security measures at commercial airports. Arguably, more has been done in since 9/11 from a security standpoint than all the previous years of commercial aviation combined. Further, as these incidents indicate terror cells constantly adapt their tactics to circumvent current security screening procedures. From passenger carried guns and hand grenades, baggage bombs, person-worn IEDs, using lanes as weapons, to attacks on airport structures themselves reactive security measures shifted focus with each changing tactic. Adaptive security measures included improved passenger and baggage screening, PPBM, K-9 bomb detection, Sky marshals, and federalization and improved regulation of screening procedures. With each distinct phase, the tactics of attackers caused procedural changes in commercial airport security.

Keywords

Airport security · TSA · Security screening

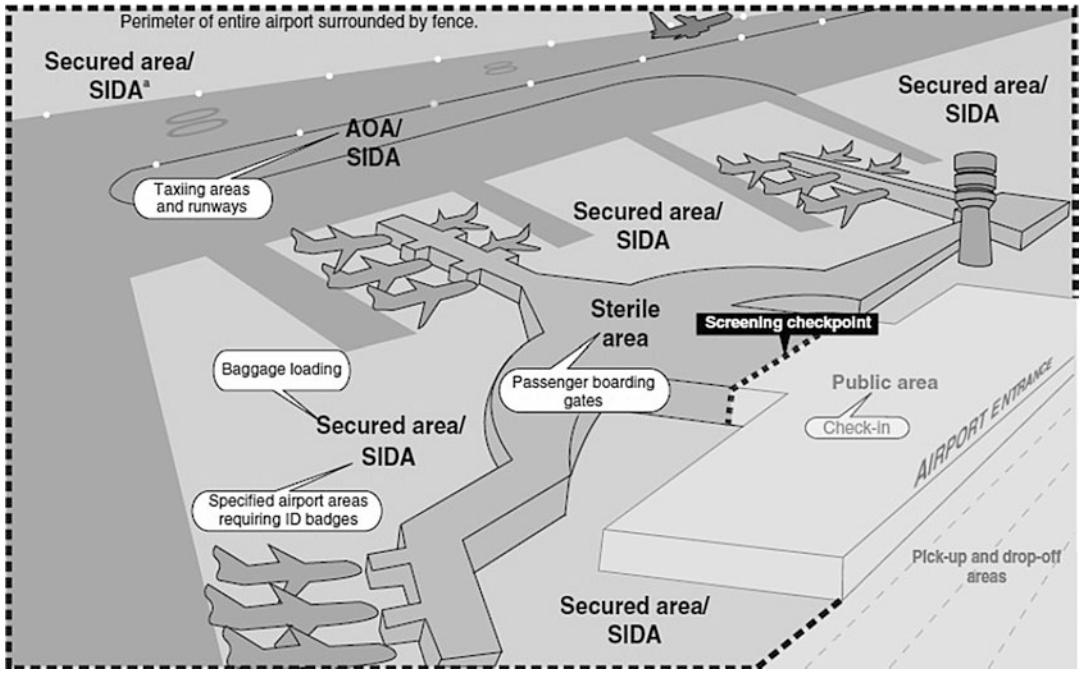
Definition

This entry explores security procedures in secured areas of airports and how governmental and private sectors intersect. Procedures in airport security have to address threats in public/nonpublic areas, in perimeter airfield locations, and within terminals. Often the private sector, with governmental oversight, screens passengers, employees, baggage, and cargo in both secured and nonsecured areas of the airport. Therefore, this entry will examine how both governmental and private security sectors regulate SIDA badge areas, credentialing systems, airport access control, airfield patrol functions, and perimeter security in secure areas of airports.

Introduction

Pre 9/11, private industry fulfilled a more substantial role in commercial transport security as airlines and airports relied solely upon private security contracts. Two months after 9/11, Congress enacted the Aviation and Transportation Security Act (ATSA), Public Law 107-71. This created the Transportation Security Administration (TSA), which federalized commercial passenger and baggage screening. Further, ATSA mandated that 100% of checked passenger baggage was screened (US Congress 2001). With new federalized regulations, private passenger screeners were hired, trained, and employed by the TSA, which became part of the Department of Homeland Security (Price and Forrest 2016). After the passage of ATSA, federal workers replaced contracted private security screeners in 450 commercial airports nationally, and the number of screeners went from 12,000 to over 40,000 in 1 year (Price 2018). Notably, ATSA outlined that TSA's primary function is to ensure regulatory compliance with airport and airline security regulations, to screen passengers, to screen bags, and to deter individuals from committing unlawful acts of interference with aviation (Price and Forrest 2016). DHS's other primary responsibilities also include information analysis and infrastructure protection; chemical, biological, radiological, nuclear (CBRN), and related countermeasures; border and transportation security; emergency preparedness and response; and coordination with other parts of the federal government, with state and local governments, and with the private sector (TSA 2006).

With augmented federalization of airport security, this lead to an altered reliance upon support from private sectors. This reliance shifted from private security agencies being responsible for most secured areas of airports to a radical shift of a blended integration with federalized agencies in security-related research and support. Currently, private sectors aid federalized security in passenger screening, personnel screening, airport access control, credentialing systems, perimeter monitoring, intelligence collection, alarm response, and detection technologies (Price 2018). This integrated merger lead to a layered intersectional approach to airport security procedures.



Airport Security: Procedures in Secured Areas for TSA and Private Security, Fig. 1 Diagram shows secured divisions of typical commercial airport. (Taken from Rabkin et al. (2004))

Presently, security procedures in airports involve the incorporation of shared responsibilities between airport operators, air carriers, private security agencies, local police jurisdictions, federal police jurisdictions, and the Transportation Security Administration (TSA). This layered approach involves distinct security procedures that occur in both unsecured (non-sterile) and secured (sterile) areas within international airports (refer to Fig. 1). Within this layered approach, there are different security threats that are addressed differently, namely, internal threats and external threats. Internally, personnel are concerns within sterile areas. Externally, criminal acts and acts of terrorism are strategic security concerns in sterile areas. As such, there are various components of airport security in sterile areas. This includes screening of passengers and carry-on luggage for weapons and explosives, screening of checked baggage and cargo for explosives, controlling access to sterile areas, clearing and badging personnel with access to both SIDA and AOA areas, and oversight of FAA inspections. Drawing upon tactics used in sterile areas (controlled by security regulating bodies), this entry examines how these current procedures uphold security in sterile areas.

SIDA (Security Identification Display Area) and Air Operation Area Restrictions

Before examining how security layering works in international airports, the first step in understanding airport security is to identify and distinguish non-sterile and sterile boundaries within an airport. A sterile area of the airport is an area that allows passenger access to boarding aircraft, and access is controlled by TSA or an aircraft operator under 49 CFR 1544 or 49 CFR 1546 if a foreign air carrier (Price and Forrest 2016). The purpose of a sterile area located prior to boarding aircraft is to provide a passenger containment area which

prevents persons from gaining access to weapons or contraband after passing through security checkpoint screening (TSA 2006).

FFA regulation Part 107, Section 205, outlines how Security Identification Display Areas (SIDA) are distinguished and regulated within sterile areas. Further, FFA regulation 107.205 authorizes airport operators to carry out measures to prevent unauthorized presence and movement in SIDA locations, establish a personnel identification system, subject each individual to employment history verifications before authorizing unescorted access to SIDA areas, and train each individual before granting unescorted access to SIDA locations. Under Title 49 CFR Part 1542, airport security policies and regulations further regulate (a) access to secured areas and sterile areas of the airport, (b) the requirement that airport personnel wear an approved access/identification badge, (c) the requirement that airport personnel challenge individuals who are not wearing the proper badge (or any badge) in security areas, and (d) the requirement that individuals maintain a proper escort of other individuals who do not have access/ID in a security area.

Monitoring of Employee Movement Through SIDA/AOA Areas

It is often a false conception that all airport employees undergo security screening before entering a sterile area (see Price 2018). Many airport workers in the United States are not subjected the same screening process as airline passengers, but instead they undergo background and criminal history checks, are issued SIDA/AOA badges, and use access-controlled doors to enter sterile areas (see 49 CFR 1542.207), where a credential check is needed. SIDA/AOA badges identify and document when workers enter/exit SIDA sterile areas in airports. Currently, American airports have debated whether all SIDA/AOA badge holders should go through the passenger screening process. As such, some airports have established screening checkpoints at airfield access gates, but private contractors working for the airport conduct employee screening, not the TSA (Price and Forrest 2016). As such, an employee's job responsibility determines their level of access authority and their level of access through access-controlled doors or physical access control systems (PACS). PACS can include locks on a keyed door, keypad locks on doors to more advanced computerized systems with integrated closed-circuit television (CCTV) with alarmed access points (Price 2018). Most of these systems are proprieties of private companies, which develop both hardware and software to manage employee access with federal oversight (Price 2018).

Functionally, only one employee at a time can use the said doors, and SIDA/AOA badges are used as encoded keys that either restrict or permit employees to pass through regulated doors. For example, emergency personnel have access (if SIDA/AOA verified) to all areas contained within sterile areas. This includes SIDA locations and Air Operations Areas (AOA), which are any location where planes land, take off, or surface manoeuver (i.e., runways, taxiways, and aprons). Yet, other members of staff who clean planes or work in catering areas may only have access to certain portions of SIDA or AOA (see Fig. 2). For some, i.e., emergency personnel with SIDA/AOA access, emergencies often supersede screening from a regulatory perspective. Yet, regulated airport access-controlled doors prevent unauthorized personnel from entering sterile areas without undergoing screening even with SIDA badge access.

By controlling who has access to which area, there is an extra security barrier in these sterile areas to reduce internal threats. Examples of internal threats within the sterile area would include the transportation of narcotics, bombing access, and burglary/larceny access to passenger areas and airplanes. By requiring a criminal background check to obtain a secured area ID, airports are arguably reducing the probability of criminality in secured areas. For example, if a prospective employee has an identified criminal history of

Secured/ Security Identification Display Area (SIDA)	Air Operation Area (AOA)	Sterile Area
All workers must display ID badges	If SIDA, all workers must display badges	All workers must display badges
Worker fingerprint checks prior to being granted unescorted access authority	If SIDA, worker fingerprint checks prior to being granted unescorted access authority	Worker fingerprint checks prior to being granted unescorted access authority
Workers not required to be physically screened before entering these areas	Security awareness training for workers	Workers must be physically screened before entering this area; however, alternative approaches can be used
Measures to detect and respond to unauthorized presence in this area	Measures to detect and respond to unauthorized presence in this area	
Signs at access points and perimeters that warn against unauthorized entry	Signs at access points and perimeters that warn against unauthorized entry	
Access control used that meet performance standards (e.g. personal identification number)		

Airport Security: Procedures in Secured Areas for TSA and Private Security, Fig. 2 Security requirements in a typical commercial airport. (Adapted from Rabkin et al. (2004))

theft, then the SIDA process can reduce the probability of granting them access to a tempting area for theft (i.e., non-CCTV areas where baggage is stored, duty-free items, alcohol, etc.).

Screening Technology Used Prior to Entering Sterile Areas

There are four major screening areas before admittance into any sterile areas of the airport: passengers, carry-on baggage, hold baggage, and cargo. In respect to passenger screening, Enders, Sandler, and Cauley's (1990) evidence-based research over the effects of metal detector screening in airports found that they reduce incidents of aerial hijacking. Gabbidon et al. (2012) further found that the usage of x-ray technologies has effectively led to a dramatic decrease in the number of aircraft hijackings. Lum et al. (2006) found that when examining security, target-hardening strategies at airports through increased detection are an effective type of intervention. Constantly evolving, these target-hardening strategies (e.g., metal detectors, airport screening, whole-body imaging, etc.) have evolved since the height of airline skyjackings since 1961.

Prior to 1972, private security officers contracted through airports and airlines performed hand searches for baggage brought aboard airplanes (Wetter 2013). With the increase in air traffic and the number of air passengers, efficiency demands changed. With the invention and adaptation of x-ray imaging of baggage during security screening, later developments of imaging technologies, more sophisticated training, and certification for x-ray screeners in airport security checkpoints screening became more accurate.

Other detailed methods of baggage screening incorporate Explosive Detection System (EDS) and Explosive Trace Device (ETD) technologies to detect explosives (McLay et al. 2009). Currently, EDS, first employed in the United States in 2002, incorporates tomography that simplifies the detection of risky items (i.e., explosives) by generating topographic images ("slices") from images taken from the interior of baggage (McLay et al. 2009). Similar to computer-aided smart x-ray, tomography employs a warning system to alert security personnel to any potential

problem area located within baggage. ETD, on the other hand, is used to detect whether there are explosives in baggage by way of chemical analysis (Ergün et al. 2017).

In respect to the screening of passengers beyond metal detection processes, the security industry has developed two major types of body security scanners: one that relies upon ionizing radiation (x-rays) or non-ionized radiation (terahertz and millimeter waves) (Wetter 2013). Non-ionizing radiation has less resolution than ionized radiation, and x-rays can be absorbed by water on the body (e.g., sweating) (Wetter 2013). Notably, screening with ionizing radiation allows for higher resolution as well as the identification of objects on the body. Obviously, this has led to privacy issues regarding their usage (see Panter 2013). In the Unite States, these scanners are routinely used, yet in the worldwide security, scanners are not an approved means for screening passengers yet due to various privacy issues.

Process of Passenger Checkpoint Screening

Preliminary screening of passengers prior to a flight occurs when the initial flight is booked. Passenger names are checked against "no-fly" and selectee lists. Passenger names are checked again a "no-fly" list maintained by the Terrorist Screening Center within the FBI which contains information about known or suspected terrorists through the program *Secure Flight*. Due to the secrecy surrounding the criteria for inclusion on the lists, a passenger on the "no-fly" list will be able to purchase a ticket but will be unable to print a boarding pass. When the individual checks in for their boarding pass at the airport, they are notified in person that they are not allowed to fly (Ergün et al. 2017). Currently, it is unknown how many individuals are actually on "no-fly" lists.

Other individuals who book a ticket maybe allowed to fly, but they are unknowingly on selectee lists. This Secondary Security Screening Selectee (SSSS) security measure begins when the letters "SSSS" or "*S*" are printed on a selectee's boarding pass. Prior to individual screening, this notifies TSA during a Travel Document Check (TDC) that a person must go through a more intensive screening process or they may be denied boarding in general. Just like the selection criteria for "no-fly" lists, it is unknown what the selection criteria for a selectee entail. Notably, during a Travel Document Check (TDC), TSA inspects and compares passenger identification against boarding passes for all individuals in screening lines. The TDC security process does not check for wanted felons, as TSA's primary objective is to prevent acts of air terrorism.

During TSA screening, if a passenger is not on a "no-fly" or "selectee" list, security screening is conducted to identify if any prohibited item is located in passengers' baggage or whether airport personnel have such substances when they are in sterile areas of an airport (Salter 2007). Therefore, in airport security procedures, hand searches are required, as well as the use of various technical devices to maintain comfort and speed of service. Security systems technology is used to screen three key elements: passengers, checked baggage, and carry-on baggage.

In passenger screening areas, physical barriers funnel passengers to a security official who conduct document verification to confirm the seat allocation/ticket matches both the passenger ID and documentation. From there, passengers place carry-on baggage into x-ray screening where contraband is detected. If any irregularities are detected in a passenger's carry-on, the baggage goes through additional screening either manually or through ETD search until the suspected prohibited item is located. During this process, the passenger is not allowed to touch the bag in question. Passenger screening is similar with the usage of different technologies. Passengers walk through either a metal detector or whole-body imaging technology. If any irregularities are detected, the passenger goes through additional screening through a hand-wand or pat-down search.

As such, criminals with passenger tickets (who are not on "no-fly" or "selectee" lists) are given access to sterile areas within the airport. Often it is incorrectly assumed that passengers in sterile areas do not commit crimes requiring airport law enforcement. Yet, criminal behavior by both passengers and staff in sterile areas is a common place in airports (see Fig. 3).

Thefts from cash facilities (banks/ATMs)	Shoplifting
Robbery of individuals both in sterile areas and upon aircraft	Domestic violence
Vandalism	Identity theft
Pickpocketing	Credit card skimming
Drunk and disorderly (intoxication)	Kidnappings
Theft from supply trucks	Rapes
Prostitution	Homicides
Child abductions	Human trafficking
Drug smuggling	Property theft (baggage, vehicle theft, etc.)
Physical assaults on airline workers	Concealed weapons
Trespassing in sterile areas	Child molestations

Airport Security: Procedures in Secured Areas for TSA and Private Security, Fig. 3 Types of crimes committed in sterile areas of airports

Process of Cabin Baggage Screening

Checked baggage screening did not start in the United States until the 1980s, and 100% of check bag screening did not occur until after the passage of the Aviation and Security Act (ATSA 2001). According to Shanks and Bradley (2005), prior to 9/11, less than 5% of checked baggage were screened. Currently the most commonly used technological device for baggage screening is x-ray. Notably, ICAO airports are required to hand search 10–20% (depending on the threat level) of cabin baggage screened by x-ray by hand (International Civil Aviation Organization, 2018).

TSA has incorporated a "screening partnership program" to qualified companies, which operate under federal oversight and comply with both TSA security screening procedures and other perimeter screening regulations. This is due to cost-efficiency, practicality, access to better technologies, or because private companies are more effective than governmental regulated operations (see Grover 2016). Markedly, an investigation carried out by the Government Accountability Office revealed that undercover agents were able to sneak mock explosives/banned weapons through security checkpoints 95% of the time when TSA was responsible for access control (see Grover 2016). As such, security experts have advocated for a more pluralized security approach that incorporates more private security employees working alongside TSA governmental employees.

Hold Baggage Screening

Prior to baggage screening, airlines at baggage check-in ask a series of questions regarding the passenger's trip and their baggage. Once the baggage is checked in, the baggage goes through primary screening in a secured area of the airport through an explosive detections system (EDS) or an explosive trace detection (ETD). Baggage may also go through alternative screening including manual searches, TSA-certified K-9 bomb detection teams, and positive passenger bag match.

Notably, ICAO airports are required to screen 100% of originating and transferring hold baggage by either hand, conventional x-ray equipment, or explosive detection system (EDS) equipment. If transferred hold baggage has a validation process and continuous implementation of procedures have been established for screening at the point of origin in secured areas, then an exception can be made. If threat levels are elevated, hand searching or advanced x-ray technology must be used 10–20% (depending on the threat level) of hold baggage after initial screening (International Civil Aviation Organization 2018). Currently there is a practical trend for hold baggage to be remotely screened because operators can sit in a control room and the images of bags are allocated and distributed by a computer to

different screeners (Wetter 2013). By doing so, this reduces idle times between images and aids screeners in keeping their concentration.

Access Control and Security Within SIDA/AOA Areas

Typically, within SIDA/AOS areas, a working interaction exists between governmental and private-run operations, which incorporate various technological into a layered security module that incorporates access control tactics and strategies. These tactics and strategies in regulating access control involve a working relationship between TSA, law enforcement agencies, and private security agencies often responsible for perimeter security. From a technological standpoint, advanced surveillance incorporates identification readers, closed-circuit television (CCTV), and perimeter intrusion detection systems (PIDS).

Plainclothes Law Enforcement/Undercover Law Enforcement

ICAO calls for the law enforcement patrol of the entire airport and its surroundings and to be available to respond to incidents of unlawful interference with aircraft or airport operations (Price 2018). Often, police personnel are provided by local municipalities (For example, during my police tenure, I was assigned to Hartsfield-Jackson Atlanta International Airport via Atlanta Police. Atlanta is the world's busiest airport based on passenger traffic (50,251,962 passengers annually) (source: www.atl.com).) or in some cases through an independent airport authority police force. As airport policing requires protecting critical infrastructure, uniformed officers are responsible for responding to security violations at checkpoints, security violations on inbound aircraft, airport employee criminal infractions, vehicular traffic, and irate passengers. As such, airport police must have good customer service skills, good observation skills, community-based tactics, and the ability to distinguish the difference between an upset traveler and a person who is an actual security threat. Besides responding to and investigating crimes in both sterile and non-sterile areas (see Fig. 3), police may conduct plainclothes/undercover proactive investigations. In larger American airports, plainclothes/undercover police often aid in larger-scale investigations involving passengers/baggage alongside federal agencies (e.g., Federal Bureau of Investigations Drug Enforcement Agency; National Security Agency; United States Customs and Boarder Protection; United States Immigration and Customs Enforcement; United States Secret Service; Bureau of Alcohol, Tobacco, Firearms and Explosives; United States Marshals Service; etc.).

Close-Circuit Television (CCTV)

Arguably, there are more CCTVs per square foot in commercial airports than other public areas. Most of these cameras are aimed at security gates, security doors, transition zones between non-sterile and sterile areas, passenger gates, baggage claims, and other publically accessible spaces. Often CCTV footage is monitored alongside security/police responses when a suspicious or heightened alert occurs, assessing unattended baggage from a safe distance, surveillance for theft/human trafficking, documentation for criminal investigations, monitoring of employee controlled access gates, etc.

Airport Perimeter Security

Airside and landside security requirements require effective security that integrates physical barriers, identification and access control systems, surveillance or detection equipment, implementation of security procedures, and effective use of resources (TSA 2006). Notably, since landside facilities are not typically affected by the operation of aircraft, it typically has less stringent security requirements than airside areas. Yet, airside breaches onto airfields through perimeter security are common (see Olivier 2014). Often these breaches are accidental, yet intentional breaches often occur for the following reasons: an attempt to chase down a departing aircraft because an individual has missed their flight, to take a shortcut from one area to another without driving around the airport perimeter, or in rare cases police chases or drunk drivers driving through perimeter gates (Price 2018). In such

incidents, the airfield is essentially shut down until the hazard is no longer considered a threat to aircraft on airfields.

Notably, when it comes to airport perimeter security, the FAA, TSA, and the International Civil Aviation Organization (ICAO) all have regulations and suggested practice (see: Olivier 2014). Unlike passenger screening, private security companies often regulate perimeter security. Unarmed security officers often are responsible for perimeter security. As such, their presence, while not law enforcement in nature, is to deter criminal behavior, report suspicious behavior, report violations of airport security, and report any signs of a threat to the airport (Price 2018).

In respect to boundary barriers located in landslide areas, appropriate security boundaries serve to minimize access points. Fencing around security area boundaries often incorporate motion, tension, or other electronic sensing that are monitored by private security sectors. TSA mandates that signage must be visible to identify boundaries between secured areas (1542.201) and AOA areas (1543.203). Based on topography, often chain link fences with barbed wires are established around said perimeters. As such, fences and their monitoring by private security sectors serve as a basic link of deterrence and defense against perimeter breaches (TSA 2006). In regard to technologies, perimeter intrusion detection systems include virtual fences, fence sensor systems, infrared video surveillance systems, visual spectrum video surveillance systems, mobile detection systems, fingerprint readers, and in rare cases unmanned ground and aerial drones (Price 2018). The private security sector, often represented by the American Society of Industrial Security (ASIS), continues to develop perimeter defense technologies along with training and certification for employees who implement said security measures (Price 2018).

Conclusion

The private sector plays an import role alongside governmental agencies that are responsible for security within both sterile and non-sterile areas of airports. Private agencies provide frontline screening and security functions that are supported with the integration of governmental employed police when armed intervention is required (Price 2018). From passenger screening, baggage screening, SIDA/AOA badge credentialing, undercover major investigations to perimeter security, both private and governmental agencies work intersectionally with the overall goal to safeguard civil aviation against unlawful interference.

Definition

Organizations serve numerous purposes: sharing of views and knowledge among members and supporters, standards setting, and numerous other services. ASIS International has been termed "foremost" among several industry organizations and associations concerned with protective assets from loss (Lipson 1975, p. 186). Now a global entity ASIS International faces existential issues concerning how it will serve future members.

Introduction

During World War II, the United States and the Union of Soviet Socialist Republics were allies against the Axis powers. But following peace in 1945, the two nations' political and economic systems diverged sharply with each superpower believing the other was dedicated to world conquest. The Cold War was born with the failure of the two former allies to agree on restructuring governments and territories mostly of Eastern Europe.

Hostilities between the two forces never led into a shooting conflict. Yet, elsewhere in the globe, the two economic and military powers saw "proxy" conflicts such as East and West Germany, North and South Vietnam, and North and South Korea. By the early 1950s, chances of a renewed conflict between the United States and

the USSR seemed depressingly almost inevitable, and such hostilities this time would involve nuclear arms with harm capable of reaching an unimagined level. Military and intelligence activities and investments were at high levels. Private security businesses were expanding, and a sector of private industry was inextricably responsible to produce what was needed for national security.

Individuals heading security programs in industries serving classified activities of the federal government were required to obtain security clearances in order to work on confidential projects. Furthermore, all employees who protected private information of national importance were also required to obtain security clearances or were barred from being on the worksite. "Proper clearances were a *sine qua non* to obtaining government contracts," wrote an industry historian (Lipson 1975, p. 44). These vetted organizations provided hardware, systems, and services to government and were bound to the same classified standards as were the secrecy-bound government departments and agencies. This military intelligence requirement set the basis for a trade and professional group that would support leadership in protecting people, property, intellectual property, and opportunity.

The Early Years of ASIS

Security specialists, often with military, law enforcement, and intelligence backgrounds, took responsibilities for organizations that had to meet government classification requirements. In November 1953, five men met in Detroit, Michigan, to exchange views on what was then called industrial security. The group represented the public and private sectors and included Robert L. Applegate, Office of the Assistant Secretary of Defense for Manpower, Personnel, and Reserve; Eric L. Barr, General Dynamics; Eugene A. Goedgen, General Electric; Paul Hansen, Reynolds Metals Company; and Russell E. White, also General Electric (Leading the Charge 1990, p. 9). The five continued to be in touch with each other to discuss their interests. The possibility or necessity of creating a national security organization evolved, a suggestion made first by Applegate. Other security groups, often concerned with local commercial matters, already were in existence but showed no interest in linking themselves with a national association where their identity could be lost.

A Special Security Group of 21 men met the next year in Cincinnati to discuss the matter further. Hansen had drafted a prospectus for the incipient organization. He argued "Industrial security and protection has become such an important part of history and national security that it should now qualify as a profession to be so recognized and takes its place along with the other great professions" (Leading the Charge 1990, p. 10).

Two existing organizations – the Industrial Security Council of the National Industrial Conference Board (today The Conference Board) and the Security Committee of the Aircraft Industries Association – joined the temporary governing body to help organize the new society. It would accept three types of memberships: Active members were the persons most responsible for industrial security and protection functions of an organization. Associate members, presumably down the pecking order, were ineligible for active membership but performed supervisory, administrative, or professional duties concerning industrial security. Then, government personnel concerned with security matters constituted a separate membership category. Proof of employment or government service was always a requirement. Prospective student members – a new category created years later – would need to provide their current transcript or bursar's receipt and express interest in security employment in order to be admitted to membership and enjoy the benefits.

In January 1955, the American Society for Industrial Security (ASIS) was incorporated in Dover, Delaware. Its charter stated in part that its purpose was: "To encourage, promote, aid in, and effect the voluntary interchange among members of the Society, of data, information, experience, ideas, knowledge, methods, and techniques relating to the field of industrial security." The charter additionally identified the intention "to promote uniformity in industrial security, as such, and

develop matters of mutual interest to its members." Ethics and professional standards would be emphasized. Publications and education would be supported. Hansen, ASIS's chief idealist, was elected the first president (Paul Hansen 1990, p. 12).

Rapid Expansion of ASIS

Within just a few months of its founding, security decision-makers from other workplaces unaffected by Cold War preoccupations and without government contracts sought ASIS membership. After all, most managerial issues did not involve matters of government secrecy. An expanded scope of vocational concerns and skills sharing attracted the evolving cadre of security directors in offices, healthcare facilities, manufacturing businesses, retailers, transporters, academic institutions, and still other workplaces. Membership, initially open to security practitioners in the private and public sectors, was enlarged to include affiliate memberships for suppliers of security services in 1957, though such members were not permitted to hold chapter offices for several years.

During the early decades of its existence, ASIS scrutinized membership applications with care. Did the applicant truly have a connection and commitment to protection of assets? Did any question arise about the loyalty of the prospective member to the interests of the United States or, as membership became more international, the ethos of the West? This vetting process and member services required a headquarters, and a logical place for it to be located was Washington, DC. ASIS would be governed by a Board of Directors who would henceforth set policies and institutional direction. The Board would also appoint someone to handle ongoing operations.

The first executive director served only 6 months in 1958. Next (1959–1964) came Brig. Gen. William Fagg (USAF Ret.). William D. Wright assumed leadership as a dip in membership was encountered and reversed it almost by double during his tenure (1964–1972). He was succeeded by O.P. Norton (1972–1977) during which time membership again doubled and emphasis on security education increased. (The O.P. Norton Information Resources Center (IRC) – a combination library, member service function, and archive – was named in his honor.) E.J. Criscuoli Jr. (1977–1993), security manager for General Electric's Valley Forge Space Center, led the organization in robust further expansion. His tenure included the purchase of land and the construction of a commodious headquarters building in Alexandria, Virginia, which opened in 1998. For the next executive director, the Board decided to retain the services of an experienced trade association executive, Michael J. Stack (1993–2015), instead of turning to an industry practitioner as in the past to manage operations. Expansion had occurred globally, and services became complex with membership peaking at a reported 38,000. The next year Peter J. O'Neil, also an organizational manager, became executive vice president and staff director.

Chapter Activity

From its earliest existence, emphasis was placed on the importance of active individual chapters where activities would be centered throughout the year. Chapters drove membership growth through vigorous networking and valuable local programs. Prominent leaders of the security community, not surprisingly, became chapter chairs. While initially affiliate members could not hold leadership roles, this rule was changed to the benefit of security products and service providers. (These business persons became financial supporters of chapters' activities.) Typically, chapters would meet monthly in season with a speaker on a topic of interest to the membership. The chapters often would publish their own newsletter, liaise with law enforcement and related agencies, support local security-related education, and sometimes hold their own annual seminar.

But a coming together for an annual national meeting was an early decision. The first annual Seminar in 1956 drew 254 charter members; by 2 years later membership had reached 2000 (Davidson 2004, p. 2). The Seminar was renamed the Annual Seminar and Exhibits to emphasize the

growing trade show activities and is now called the Global Security Exchange (GSX). The event spans over almost a week and combines education, technical exhibits, commercial displays, and society business. For many security leaders, attending this event is the highlight of their year in a vocational sense. Increasingly over time commercial exhibitors also used the meeting to announce and promote their latest offerings. Eleven corporations exhibited at the first seminar; in recent years over a thousand are registered.

A quarterly magazine, *Industrial Security*, was launched in 1957 as a member benefit. Over the years it became bimonthly and then monthly and was renamed *Security Management*. Meanwhile, from a fledgling start, chapters expanded to over 240 (103 international). Regional vice presidents, themselves usually former chapter leaders, would coordinate activities of chapters in their geographic regions.

Nonprofit Foundation

In its search for professionalism, ASIS established a nonprofit Foundation in 1969 to support education and research in the field. Its first major project was a survey of security executives identifying their reporting patterns and work backgrounds (Kakalik and Wildhorn 1974, p. 75). It identified that in larger firms, the principal background of a security executive was in business, followed by law enforcement and military. Another endeavor of the Foundation resulted in the founding of a vetted research quarterly, *Security Journal*, begun in 1989. (The Journal remains important in the field but is not published by ASIS.) Charles H. Davidson, IV, Foundation staff director from 1985 to 2001, argued in the first issue that security management was "a new discipline" and deserved to be regarded as "a stand-alone" management science (Davidson 1989, p. 3).

The Foundation periodically sponsored conferences that brought together leading security practitioners and security educators to share with each other what they knew and what was still needed to be done. Years later research grants were awarded on a competitive basis to scholars who would produce a monograph on a topic of importance to the membership. These would be published and disseminated as CRISP (Connecting Research in Security to Practice) Reports, available to the membership and wider community.

The Foundation also listed an early duty: "To purchase all relevant book titles in English and in selected foreign languages, to catalog, abstract, and store them at the Foundation's headquarters, and to finance or assist in financing of distribution of such abstracts to interested persons" (Poised for Greatness 1990, p. 86). These began to fill the shelves of the O.P. Norton IRC and a vast security book, film, and research report global lending library began service in 1984, soon under the longtime leadership of Eva Giercuszkiewicz.

Certifications

From its inception, the security industry was developing a "body of knowledge," once collected by James D. Calder, the University of Texas at San Antonio, in a database at the behest of the Foundation. Knowledge of results from vetted research, best practices know-how, and formal standards were becoming expectations of competent practitioners, as was the need to establish criteria for experience and examination.

Recognizing such learning and competence for security practitioners would occur through certifications. The concept, nurtured over 15 years to fulfillment by Timothy J. Walsh and others, led to the creation of a process to "recognize achievement and encourage practitioners to expand their knowledge" (The Mark of Professionalism 1990, p. 97). This decision led to the establishment of formal certification.

The Society created an independent Professional Certification Board (PCB) that painstakingly created, with outside assistance, protocols for exam admission and an examination which, when passed, would lead to a designation as a Certified Protection Professional (CPP). The first examination was in September 1978 (The Mark of Professionalism 1990, p. 98; Criscuoli 1988, p. 98). About 1000 early designees were "grandfathered in" at the commencement, based on their years of demonstrated experience as security practitioners; a few others opted to sit for the exam despite their experience.

As the examinations became required and regularized, just being allowed the opportunity to sit for the examination represented a challenge for some. Applicants needed to provide their credentials. Probity among those designated as certified was emphasized by a CPP Code of Professional Responsibility adopted in 1975.

Two other certifications were introduced in 2003, to recognize qualified security personnel with demonstrated proficiency and advanced technical knowledge. The Professional Certified Investigator (PCI) recognizes expertise in evidence collection and case preparation. The Physical Security Professional (PSP) identifies the capacity of a practitioner to conduct threat surveys, assure knowledge of security products and technology, and design integrated security systems. All PCB-developed certifications required a commitment to ongoing learning and professional development with verified recertification required every 3 years.

Further Developments

Security activities cut across a broad range of commercial, industrial, institutional, and governmental endeavors. Everything from A to Y (academic programs to young professionals) has security concerns that are particular to them while also sharing general issues with all security endeavors. Beginning as committees, 34 ASIS Councils have been created to bring specialists together sharing their common concerns, to sponsor programs for the annual seminar, and to serve as media contacts. A Chief Security Officer (CSO) Center Advisory Council was created with the goal to link interests of practitioners of large organizations.

When ASIS was in its early years, few managerial vocations were more male dominated than security. But times changed and women began assuming leadership roles. As law enforcement organizations began drawing, if not welcoming, women into their ranks, the same thing was happening in security. With women composing a significant factor of workplace personnel, it was a natural evolution for security programs to employ females as employees, managers, and executives. This notion came to be reflected at ASIS including at the senior level. The first female president of ASIS was Darlene Sherwood, 1985, and then Mary S. Rawle, 1992. They were followed by others: Cynthia P. Conlon, Bonnie S. Michelman, and Shirley A. Pierini. Moreover, women have served as past presidents of the PCB and ASIS International Foundation.

Early in its history, the original name became problematic, and a new name and focus were needed. It was no longer just *American*, as chapters all over the world were operating (currently 108 international chapters). The first ASIS security symposium was held in Brussels, Belgium, and Paris, France, in 1973. Then the word *Society* was an encumbrance for organization that thought of itself more as a professional group. Finally, *Industrial Security* spoke of a time when "plant security" for organizations churning out classified products and systems was the basis of the young ASIS. In 2002, the name was officially changed to ASIS International. A new logo was approved by the ASIS Board of Directors reflecting the way ahead: "Advancing Security Worldwide."

ASIS International: Quo Vadis?

Regardless of relevance, organizations have to be run effectively, especially so in a vocational activity some referred to as a "management science." Yet, throughout its history, ASIS has periodically experienced budget shortfalls. "We were broke," said Dennis Chesshir, president for the 1975–1976 term. He recalled "talk about dissolving the Society" despite a growing membership, a vigorous Annual Seminar and Exhibits, and 20 years' operating experience (Davidson 1989, p. 82). From 1970 to 1979, revenues grew six times, but expenses sometimes were greater. The decade of the 1980s saw more than a triple of revenues with expenses, fortunately, always a bit less. By the end of the next decade, membership topped 30,000 with positive financial net most years to create some reserves. Seminar revenues far outpaced the importance of other income streams: publishing, membership fees, educational charges, publishing and merchandise revenues, and certification fees.

At the annual meeting of 2015, ASIS President Dave N. Tyson, retiring from the hectic annual 1-year term of leadership, reported that the

organization was strong on all levels. "Today, I celebrate not only our 60 years, but also our exciting future," he exclaimed (Exceptional ASIS Members 2015, p. ?). But earlier financial reports, unknown to the vast number of members, told a different story, one of a budget out of balance. In 2013, IRS filings revealed a budget deficit of $1.6 million – up almost ten times over the previous year – on total revenues of $29.3 million. [That year 99 individuals were employed at headquarters – national and chapter officers are not paid – while the reported compensation of the top seven amounted to $2.2 million.]

Conclusion

ASIS International would have to limp before it could walk again. The Board responded with alarm by cutting historic services. Numerous employees and their positions were jettisoned with replacements in some cases of new individuals without industry experience. The ASIS Foundation stopped activities with only the name being retained. The IRC was closed with books and other materials, assembled over decades, being boxed for an uncertain future. The ASIS headquarters building that had grown enormously in value was put up for sale. ASIS International surely has a future, diminished on the national level, but remaining vigorous within many chapters. A strong national organization is needed to advance public-private cooperation, security standards, and goals, support ethics, and interact with legislative issues that impact protection activities.

Troy University, Troy, AL, USA

Keywords

Power of arrest · Seizure · False arrests · Private arrests · Probable cause · Reasonable suspicion

Definition

Although there is no consensus over the definition of arrest, the US common law draws that arrest takes place when a legally authorized person, such

as the police, private security, or citizen, puts an individual under custody, especially because of his/her involvement in a crime.

Introduction

In criminal justice, arrest is an important outcome since it produces serious consequences on people's liberty and the criminal justice process. Arrestees, in many instances, are subject to searches on their persons and immediate surroundings. Arrest policies and how they are performed are highly associated with the level of the correctional population (Bittner 1967; Engel et al. 2017). For example, mandatory arrest policies for domestic violence are expected to increase the jail or prison population of this crime. Also, arrest decisions, when they are false or unlawful, can lead to wrongful imprisonments, as well as civil cases and criminal charges against responsible parties. As some research findings show, only a smaller number of arrestees are transferred to courts from the police, and only a minor portion of them ends up with incarceration. This finding indicates how the number of false arrests in the United States could potentially be high. The power of arrest is predominantly attached to law enforcement agencies, particularly to the local police; however, private security officials and citizens have also authority to make arrests under certain circumstances. This entry examines the definitional issues of the arrest, the power of arrest carried out by the public police and private security, and the circumstances under which arrest decisions are lawful/unlawful.

The Fourth Amendment, Seizure, and Arrest

A considerable number of scholars have been using the police arrest outcome as a major variable of interest in their studies, particularly to explore explanatory factors in police discretion, behavior, and decision-making process. On the other hand, there are still debates that hover around the definition of arrest. Studies emphasize the ambiguous aspects of arrests, such as the timing and conditions (when and how it starts). A major explanation for this ambiguity and complexity is that there is no unique definition of arrest (Center for Police Research and Policy 2018). First, the word arrest is never seen in the Fourth Amendment of the US Constitution. Second, the Supreme Court does not provide an exact definition of arrest.

The Fourth Amendment, whose main purpose is to protect citizens from "unreasonable searches and seizures" of government officials, uses the word "seizure." On the other hand, the seizure has a broader meaning than arrest. Law enforcement seizures can involve both properties and individuals. For example, upon a successful search, law enforcement officers can seize stolen cell phones as well as the owner of the house for keeping these stolen materials.

Under the Fourth Amendment, seizure takes place when law enforcement officers willfully infringe restraints on a person via using force or showing their authority. Restraint can be measured as the level of perception of a rational person in that she or he should not abandon the scene because of the officer's presence (Worral and Schmalleger 2018). In this context, the major question for a person's seizure is whether a rational person perceives that he/she is free to abandon the scene when a police officer stops him/her. If the person does not feel that he/she is free to leave the scene, there is a situation of a seizure.

On the other hand, a person's seizure and arrest do not carry the same meaning, that is, every arrest is a seizure, but the reverse is not true. For example, police stops – even though only less portion of them end up with arrest – would be considered seizure but not arrest. The restraint level of people's seizure is changeable; some are less intrusive and take less time compared to others. In this perspective, based on the literature, people's seizure can be examined under two categories: stops and arrests. To better understand the power of arrest, it is necessary to have a close look at the legal infrastructure of the two concepts and how they differ from each other.

Stops and Arrests

Within the context of the Fourth Amendment, stops can be defined as a concise restraint of a suspected person for a crime. However, arrest requires "a detention exceeding the dimensions

of permissible stop" (Clancy 2003, p. 129). Stops are, compared to arrests, less intrusive and take a shorter time than arrests and end up with less serious consequence for the subject. Although the difference between the two appears easy to understand, there is a tiny line between them in terms of when a stop is to be assumed an arrest or vice versa.

The common law in the United States has played a prominent role in constructing the legal definition of arrest for several centuries. However, the variable nature of the common law across jurisdictions has led to a flexible legal definition. Despite this flexibility, two prominent components of arrest can be drawn from the common law: (1) custody of the suspect, and (2) intent of the officer (Clancy 2003). Detention refers to putting the suspect under custody that starts with two conditions. First, it starts upon the law enforcement officer touching the subject. This gives a clear message to the subject that he/she cannot abandon the scene. This is, in fact, a manifestation of the officer's intent that the suspect is under custody. Second, custody may also be initiated when the subject submits to the officer's order. The second component is the officers' intent to arrest. From this perspective, arrest is not a random activity by law enforcement officers. An officer's actions to take the person under custody should be intentional. Officer's intent to arrest a person might manifest itself in certain forms such as providing a notice to him/her that he/she is under arrest or physically touching the suspect.

Legal Justification

According to the Fourth Amendment, law enforcement officers should have a justification to carry out searches or seizures. Justification is simply a suspicion. The degree of suspicion depends on the level of intrusion that the law enforcement agency performs. In other words, the law enforcement agency needs to show a stronger justification when performing a higher-level intrusion on citizen freedoms. In this case, there are two types of justification for people's seizures, each of which corresponds to different intrusion levels. These are probable cause and reasonable suspicion.

The word probable cause appears in the Fourth Amendment; however, reasonable suspicion entered the literature with the Terry v. Ohio (1968) Supreme Court decision. According to the Supreme Court definition, mere suspicion is not enough for a probable cause. Probable cause is valid when "the facts and circumstances within [the officers'] knowledge and of which they [have] reasonably trustworthy information [are] sufficient to warrant a prudent man in believing that the [suspect] had committed or was committing an offense" (Worral and Schmalleger 2018, p. 170; Beck v. Ohio, 379 U.S. 89 (1964), p. 91.). In this context, it can be established that, as the more intrusive form of seizure, arrest decisions require probable cause rather than reasonable suspicion. Many probable cause examples can be proposed; for example, a police officer can arrest a person who attempts to flee from the scene or carries incriminating evidence on his/her person.

In reasonable suspicion, however, the certainty level of suspicion that the suspect committed an offense or was committing an offense does not have to be so high as the one in probable cause. In fact, the majority of daily police activities, such as traffic stops or Terry stops, do not involve such a strong police suspicion and intrusion. Worral and Schmalleger (2018) quantify the certainty level of suspicion in probable cause situations as higher than 50%, but this level in reasonable suspicion situations lies between more than 0% and lower than 50%. Based on reasonable suspicion, police officers can stop and frisk drivers and passengers but, however, cannot arrest them. It is necessary to note that the police could carry out arrests during stops and frisks, but these arrests should still be relied on the justification of probable cause.

Arrests With/Without a Warrant

As a general approach, law enforcement agencies are encouraged to perform with-warrant arrests, but this is not required since, in many situations, getting a warrant is unachievable. Under exigent circumstances, for example, when a police officer encounters a thief attempting to steal a car, an arrest warrant is not required. In addition, where the arrest takes place is also the other factor that

determines whether a warrant is required or not. The police are not required to have a warrant when making an arrest in public places upon a probable cause. However, except for certain circumstances and the owner's consent, the law does not permit law enforcement officers to enter private homes without a warrant (Worral and Schmalleger 2018).

Therefore, if arrests are to be made in private or particular places, this requires a warrant and has to meet three conditions. First, the warrant should be given by an objective judge. Second, the law enforcement officials should have a probable cause to believe that the person is involved in a crime, and third, the suspect should be sufficiently described. Only the name is enough for the description of the offender but is not necessary if the law enforcement could determine the location of the suspect. In this case, the arrest warrant is arranged on the name "Joe Doe" and should contain very specific description of the suspect (Worral and Schmalleger 2018).

Private Arrests

Both the public and private police (including citizens) can make arrests in the United States even though the strength of power to arrest that derives from the legal framework is varied. The public police receive their authority directly from the constitutional law as well as the common and statutory law. However, private arrests are not based on the constitutional law; therefore, the common and statutory laws constitute the foundation of private arrests (Nemeth 2017).

Like the public police, private citizens have a power to arrest a person (1) if they observe that the person has committed a crime and (2) if they have a reasonable belief (probable cause) that the person committed or is committing a crime. The citizen's presence during the commission of crime is required in the first condition, but not required in the second one. Also, the authority to arrest made by citizens is changeable across jurisdictions and crime types (Nemeth 2017). For example, in New York, if the offense is not a felony, a citizen can arrest the perpetrator only within the county where the crime takes place.

In this context, private security officers have the same degree of authority as ordinary citizens to arrest a suspect. The difference between them is that private sector and business owners delegate the right to protect their property to security officers in return for money. In other words, the basic function of private security officers is to shield their employer's property (see chapter ▶ "Police: Public Versus Private Policing" in this encyclopedia). In addition, private security officers and citizens, when carrying out an arrest, are largely responsible for holding the suspect and preserving the evidence until the public police arrive (Roberson and Birzer 2010; see chapter ▶ "Private Detectives" in this encyclopedia).

False Arrests

False arrest is the unlawful detention of a person in that it occurs in the absence of probable cause or court order. That is, the arrested person can only be detained because of a suspicion that he/she committed or was committing a crime. The person cannot be apprehended as a result of only a bare suspicion. While the Fourteenth Amendment gives the authority of arrest to merely law enforcement officers, according to the common and statutory law, citizens and private sector security officers can also make arrests. Therefore, in addition to the public police, private security officers and citizens are liable for false arrests. For example, false arrest cases are most commonly encountered in shoplifting cases in which store employees or security officers detain a person for stealing something. A raising question is whether private security officers are under the mandate of the Fourth of Amendment demands when arresting such a person. The Burdeau v. McDowell case indicates that private security is not under the mandate of the Fourth Amendment (Nemeth 2017). However, this does not mean that probable cause for private security/citizenry arrests is no longer valid. According to Nemeth (2017), private citizens should have to provide a strong justification for arrest decisions. For example, citizens can generally make arrests when the offense is committed in their presence, and this has to be justified. Regardless of whoever makes it, the false arrest is an issue of a civil case that allows victims to file a lawsuit to recover the damage.

Conclusion

This entry discussed the definitional and power of arrest issues based on the legal framework in the United States. Arrest decisions have been the subject of research and particularly under intense investigation since the discovery of police discretion in the 1960s. Despite the presence of much research, it can only be drawn a general framework around what constitutes arrest rather than an exact definition of it. The Fourth Amendment of the US Constitution never uses the arrest word, so scholars have been trying to explain the concept of arrest based on the common law which is varied across jurisdictions. The common law draws two major components of arrest: detention which is putting the suspect under custody and the officer's intention to arrest the subject.

Neither stops nor seizures exactly meet the definition of arrest. It can be said that arrest is meaningfully narrower than seizures but broader than stops. Law enforcement seizures involve properties as well as people, and people's seizures can also be examined as stops and arrests. Arrests are more intrusive and take longer time than stops, therefore requiring a higher level of legal justification, that is, probable cause. Probable cause is more than mere suspicion. Although the police can stop persons based on mere suspicion (reasonable suspicion), they should have a probable level of suspicion in arrest decisions.

In addition to the public police, citizens and private security officers can also make arrest under certain circumstances. From a general perspective, private sector officers have the same degree of authority to arrest as citizens. Private security arrests majorly rely on the statutory law but not the constitution; the scope of them is changeable across jurisdictions. On the other hand, whoever attempts to make an arrest has to be tied to probable cause. Otherwise, it could result in false arrest situations and end up with lawsuits against responsible parties.

Keywords
Big Data

Definition

Big Data is a term used to refer to data that exceeds the capacity of traditional databases and does not easily fit into the structure of traditional databases.

Introduction

Big Data is a term used to refer to data that exceeds the capacity of traditional databases and does not easily fit into the structure of traditional databases. The need to accommodate data of this scale and nontraditional structure appeared with the advent of event streams (such as network event logs of systems with millions of users), large deployments of sensor data, archiving and indexing of the entire World Wide Web (WWW), and visual streams of high-resolution satellite data covering large areas. Such sources can easily generate terabytes (1 TB = 1000 GB) of data if not petabytes (1 PB = 1000 TB).

Using a traditional SQL-based Postgres database for comparison, Postgres version 9, had a limit of 32 TB per table. In 2008, Yahoo claimed to have the largest Postgres database in the world with a size of 2 PB. By 2009, Yahoo was claiming a modified Postgres-based datawarehouse was managing 6 PB of data (Ahuja et al. 2009). Even in this case, an individual entry in a Postgres database is limited to a size of 1 GB. Meanwhile, high-resolution, uncompressed image formats such as TIFF can approach sizes of 4 GB. This means that new architectures were needed to accommodate the rapid exponential increase in data.

Big Data Structures, Architectures, Designs, and Models

Big Data became the umbrella term for developing infrastructure that accommodates these incoming streams of large data. Furthermore, the structure of the data itself is assumed to be large, flexible, and changing avoiding many of the structural limits of traditional database tables, for example, limits on the number of columns.

Big Data transcends the traditional limits of traditional data warehouses by no longer relying on fixed columns for data and indexing data across multiple servers through distributed hash tables, allowing their size to scale.

Big Data storage architectures are distinguished by many if not all of the following features:

© Springer Nature Switzerland AG 2021
L. R. Shapiro, M.-H. Maras (eds.), *Encyclopedia of Security and Emergency Management*,
https://doi.org/10.1007/978-3-319-70488-3

- Support for storage of unstructured data
- Support for tables with an unfixed, unset number of columns
- Distribution of large tables split into "shards"
- Replications of data or "shards" across nodes in a Big Data
- Scalable architecture to support expansion of data capacity with added servers
- Performance architecture to support fast streaming incoming data

The design of Big Data systems supports "horizontal scaling" – that is, Big Data systems can expand their storage adding additional nodes to the Big Data network, as opposed to "vertical scaling," where additional storage and power is added to existing nodes.

The horizontal scaling inherent to Big Data means that data may be spread around thousands of nodes and Big Data systems need to tolerate the possibility of node failures or node network partitioning. Acceptance of node failure also means that data must be replicated across several nodes in the network. "Partition tolerance" in Big Data systems means that data may be inconsistent or unavailable during network partition events. The tradeoff between consistency, availability, and partition tolerance is known as CAP Theorem, the concept that a distributed database system can only have two out of those three. Since Big Data systems require partition tolerance, all Big Data systems offer either consistency or availability, but not both.

Tradeoffs between consistency and available in Big Data architectures depend on whether the structure of Big Data nodes are organized in a hierarchical architecture or a flat architecture.

The distributed nature of Big Data systems allows for ease of distributed parallel computation, so technologies like MapReduce, which process and aggregate data, are easily integrated with Big Data distributed storage and computation architectures like Hadoop, which support scaling storage across many nodes and managing resources.

The data model of Big Data systems differs from traditional SQL-based Relational Database Management Systems (RDBMS) in that the schemas and data models in Big Data are not designed to optimize on reducing redundancy. Among other reasons, this is why Big Data systems are referred to as NoSQL ("Not Only SQL") databases. NoSQL schemas account for storing less structured data than RDBMS data and so there is less need and less inclination to form optimally efficient schemas. Instead, a NoSQL schema will be optimized for ingesting and querying the data, both of which can be performed quickly and can be scaled upwards easily, so reducing redundancy is not a priority.

Since schemas can be flexible, they can be published and versioned by the Big Data server. These can be timestamped values associated with a single key, so a conceptual "row" indexed by a row key will have a varying number of columns themselves keyed by timestamp to a value. Alternately, a schema can be a set of key-value pairs, indexed by an index key. Varying columns with timestamps are a feature of Cassandra, optimized for streaming data ingestion, while key-value pair schemas are a feature of MongoDB, which is optimized for document storage and indexing.

Flexibility of schemas allows easy access to data from heterogeneous Big Data systems which can be accessed via a "data lake," so that regardless of the source of data, which may be stored in any number of different architectures, organizations can access data quickly. With a unified data lake interface, an organization can support decentralized Big Data systems whose owners may have unique schema and technology needs.

Conclusion

The order of magnitude increase in the scale of data requires new database architectures for storage because traditional architectures were unable to handle that level. Scalable Big Data architectures and a rethinking of how data is stored and organized enable the ability to handle this exponential increase in volume and diversity of types of data.

Definition

Authentication: Process to verify the identity of a request to access confidential information or service. It confirms if the requester is authorized to access and if so then what the privilege is.

Biometrics: Biological characteristics of an individual that are unique to the person and don't change significantly over time and environment.

Cryptography: Process a given message to a form that an unauthorized person cannot interpret but an authorized user can retrieve the secret message.

Security: Protection of information and system from unauthorized access, modification, or destruction.

Steganography: Process to hide confidential information inside another public information, including an image.

Introduction

Biometrics is the science of measurement and statistical analysis of an individual's physical and behavioral characteristics (Das 2019). It has been observed that every human being has a set of unique biometric features, which can be utilized to identify the person. From the very beginning of human civilization, some sort of biometrics has always been used for identification and authentication purposes. The way we recognize any of our family members, friends, or colleagues involves biometric technology, where our brain is first trained with the biometric features of the person and then it compares with stored information to identify the person. With the growth of technology, biometrics has become a crucial part of authentication and recognition processes, and, therefore, almost every system in society is incorporating biometrics (Campisi 2013).

The objective of this chapter is to present the basic principle of biometric technology. Different types of biometric features will be discussed, and then applications of biometrics in different sectors will be presented. Challenges and prospects of biometric-based technologies will be investigated.

Types of Biometrics

There are two types of biometric features as stated below:

1. **Physiological characteristics**: Unique feature in the construction and components of an individual body. These are the features with which a human being is born and hence usually

cannot change, which include the following (Das 2019):
(a) Face
(b) Fingerprints
(c) Finger geometry
(d) Hand geometry
(e) Iris
(f) Retina
(g) Ear
(h) Vein
(i) Odor
(j) DNA
(k) Voice
(l) Facial thermography

2. **Behavioral characteristics**: The features that an individual develop as he/she grows up. These are also affected by the environment around the individual and include the following (Das 2019):
(a) Handwriting and signature
(b) Typing patterns and key strokes
(c) Walking gait and other gestures
(d) Speech

Figure 1 illustrates some of the biometrics used for identification and recognition purposes. Each of these biometric features has advantages and disadvantages in terms of universality, reliability, efficiency, and complexity of applications (Prabhakar et al. 2009). A comparison of different biometrics is presented in Table 1.

Principles of Biometric System

Biometric technology usually operates in two phases, enrollment and identification. The enrollment phase as depicted in Fig. 2a registers individuals into the biometric database. A sensor scans the individual's biometric characteristics and outputs a corresponding digital signal. Based on the biometrics, different features are then extracted and stored in the database. The identification phase illustrated in Fig. 2b also involves a biometric sensor to scan an unknown individual's biometrics, where from necessary features are extracted. They are then compared

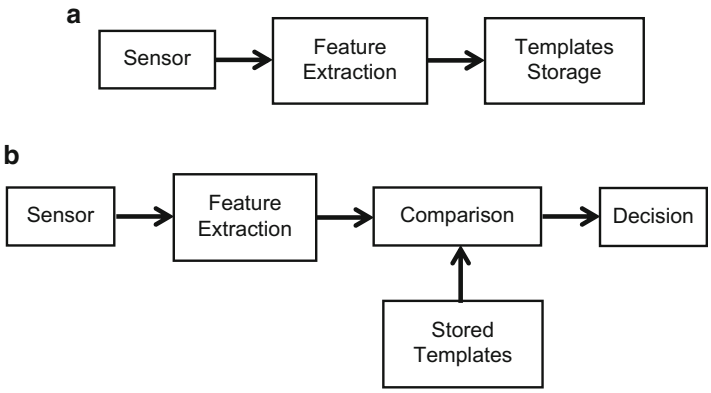
Biometrics, Table 1 Comparison of biometrics (Prabhakar et al. 2009)

Characteristics	Fingerprint	Face	Iris	Voice
Accuracy	High	Low	High	Medium
Ease of use	Medium	High	Medium	High
User acceptance	Low	High	Medium	High
Permeance	High	Medium	High	Low
Performance	High	Low	High	Low
Universality	Low	Low	High	Medium



Biometrics, Fig. 2 The basic principles of biometric-based technologies: (**a**) enrollment and (**b**) identification

against the features stored in the database to find a potential match.

Authentication Using Biometrics

Authentication is the process of verifying the attribute claimed to be true by an entity requesting access to a system. Usually it is the act of confirming the identity of an individual by validating the attributes presented. Reliable user authentication is crucial to individual, corporate, and state functions in order to avoid loss of confidential information, compromise of data integrity, and unavailability of service.

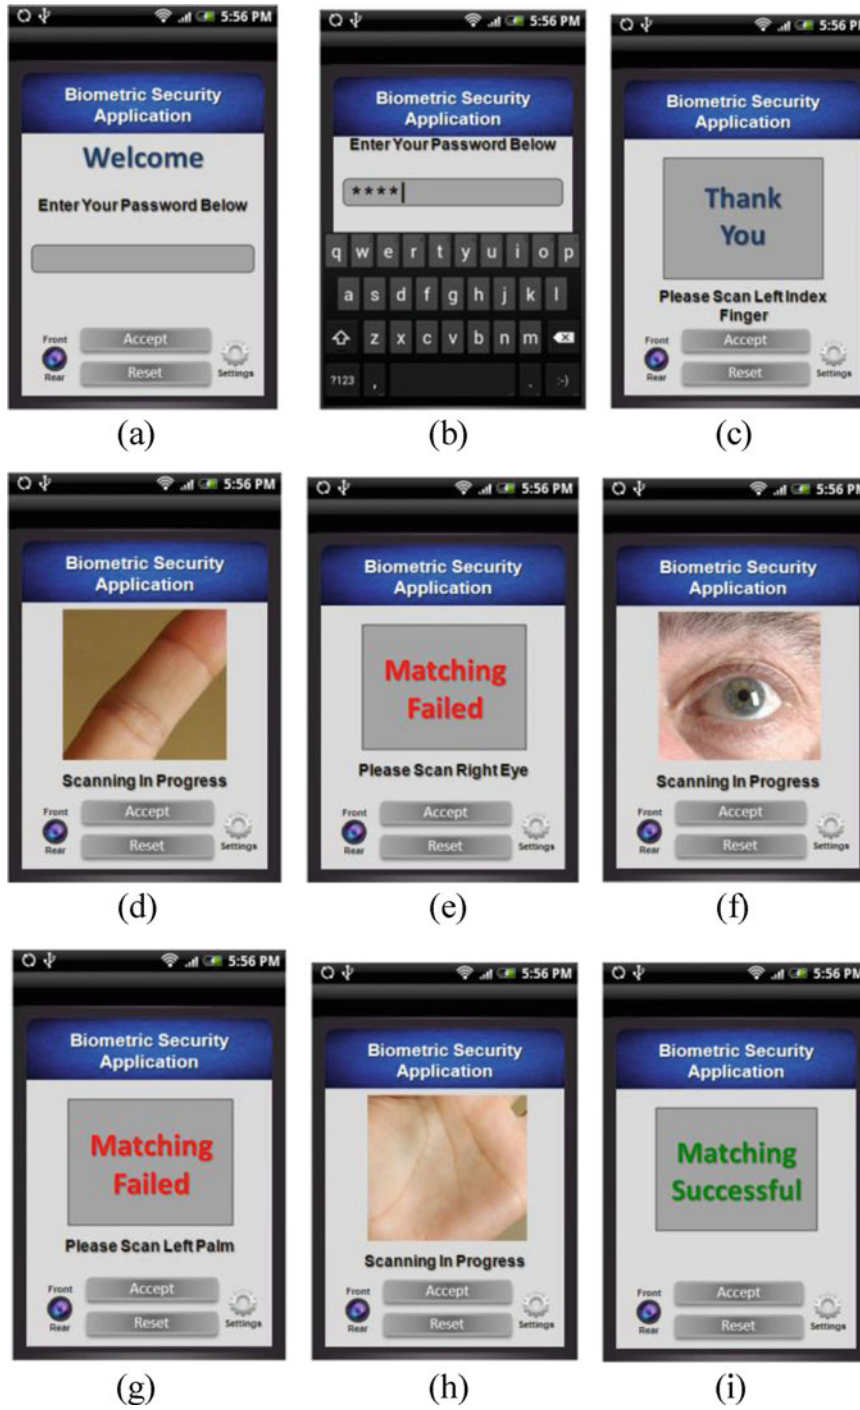
There are three factors of authentication that can be used to authenticate anyone (Stallings and Brown 2018):

(a) Knowledge: It includes something the individual knows, for example, password, pass phrase, personal identification number, challenge response, and security questions.

(b) Ownership: It involves something the individual possesses, for example, ID card, security token, and smart card.

(c) Inherence: It incorporates some unique feature of the individual that anyone inherits. Different biometrics are utilized as the key factors for authentication.

Knowledge-based authentication method suffers from individual memory, selection of poor passwords, sharing information with family or friends, and illicit acquisition by intruders. Ownership-based authentication method is becoming unreliable because of document fraud and loss. Biometric authentication has proven to be the most efficient and reliable technology (Ratha et al. 2001). The most important advantage of biometric authentication is that an individual does not have to memorize or carry anything (Campisi 2013). Recent developments in biometric technology have made the authentication process accurate, easy to implement, and very fast for automated real-time applications. As a result,



Biometrics, Fig. 3 Comprehensive authentication system developed for Android smartphone: (**a**) user is prompted for personal key such as password, (**b**) password is entered using keypad, (**c**) prompt for first biometric signature capture after successful password is provided, (**d**) first biometric signature is scanned, (**e**) feedback from the system prompting failed authentication and second try, (**f**) second signature is scanned, (**g**) feedback from the system prompting failed authentication and third try, (**h**) third signature is scanned, (**i**) successful authentication prompt (Islam 2012)

biometric authentication is becoming an increasingly important component for access to any secure facility from personal to state property.

A comprehensive authentication system can be developed to ensure the highest security and most reliable performance by incorporating different factors of authentication. Figure 3 shows an example of comprehensive authentication process developed for robust mobile computing applications (Islam and Islam 2012a).

Security of Biometrics

A great challenge with biometric-based systems is the preservation of biometric information while in storage, transmission, or processing phase (Chen and Chandran 2010). As majority of the authentication processes involve communicating with a server at a remote location either for accessing the database or sending authentication results, there is a huge vulnerability of biometric information being intercepted by intruders while in transmission. Digital encryption techniques can be applied to protect biometric information (Islam 2011). Biometric features are encrypted using a secret key and then stored or transmitted over a communication channel. An intruder cannot access encrypted biometrics for illicit use. To further enhance the security of biometrics, steganography techniques can be incorporated along with cryptography tool (Islam and Islam 2012b). Steganography is the process of hiding data inside other data which can be open to public. The most popular technique is hiding the data inside an image, where the least significant bit of the image is replaced by the corresponding biometric information bit. Figure 4 shows an example of a

Biometrics, Fig. 4 Biometric security system incorporating encryption and steganography techniques: (**a**) fingerprint, (**b**) iris, (**c**) signature, (**d**) image without any hidden information, (**e**) image with 12 hidden biometrics (Islam 2012)

biometric security system employing both cryptography and steganography. A total of 12 biometric information are used including 6 fingerprints, 3 iris, 2 personal identification, and 1 handwritten signature. They were encrypted and then hidden inside an image which demonstrates a robust and reliable security performance as shown in Fig. 4.

Challenges of Biometrics

Though biometrics offers a highly accurate and reliable authentication performance, there are a number of technical and security challenges. Some of them are listed below (Campisi 2013):

1. **User cooperation**: Biometric-based systems require individuals' cooperation in providing biometric signatures. Challenges in this regard are the following:
   (a) Uncomfortable using the devices or coming close to sensors.
   (b) Unwilling to share biometrics for storage in the system database and processing by any agency.
2. **Universality**: Receiving the same biometric signature at any time and any environment. Challenges include the following:
   (a) Some of the biometric features vary or even get distorted over time. For example, fingerprints may be less visible or recognizable, especially for working people. Handwriting changes significantly with time.
   (b) Partial biometric signature may be captured because of individual's costume or lighting condition.
3. **Processing of biometrics**: There have been a significant amount of research and development being carried out to develop efficient and fast algorithms and equipment for extracting biometric features and comparing with database templates in real time.
4. **Volume of data**: Biometric information involves a huge amount of data. Storage and transmission of such data is a great challenge.
5. **Security of biometrics**: As discussed earlier, biometrics need a high level of security.

Conclusion

Biometrics offers a great option for secure, robust, and fast authentication and identification applications. With further research and developments, biometric technologies will evolve as essential tools for almost every system in our personal and professional activities.

Definition

Border security is the step that nations take to prevent people or items from entering and departing into their country that may pose a threat or other adverse consequences or otherwise violate that nation's laws.

Introduction

One could argue that borders have been around since humans first began to settle in fixed locations, claiming that location as their own. As humans moved from hunter-gathers to agrarian society, they began to mark land over which they believe to have exclusivity over its use. These lines of ownership or borders could exist only in one's mind, meaning that this is what this person or group of people believed to be theirs, accepted by others outside their borders, based on physical features of the earth, or barrier such as primitive fences or walls to mark their land. Today, borders most commonly thought of as the divide between political entities, usually between countries. Just like in early times, these borders could be imaginary, existing only in the mind of certain individuals, borders that are agreed upon, and demonstrated by lines on a map based on conquest, threat, agreements with others, natural physical feature, or walls and other means of marking territory. Just like early man marking their territory, borders have become a symbol of national sovereignty where that nation exerts exclusive control. Borders represent national sovereignty that need to be protected and controlled to maintain that country's sovereignty; therefore, border security is an important component of any country's national or homeland security (Phelps et al. 2014).

Throughout much of history, the primary threat to border security was military incursion from hostile neighbors or other foreign forces. In fact, just a quarter of a century ago, what Winston Churchill famously referred to as an "Iron Curtain" divided Europe between East and West. The North Atlantic Treaty Organization (NATO) was founded at least in part in response to the threat posed by the Soviet Union and Soviet expansionism. As a result, in many parts of the world, much of what would be considered border security was handled by countries' military organizations (Cozine 2016). However, the use of military power against another state may no longer be the practical option if these two opponents are both militarily and economically powerful. The cost of war can become a high one, not just in the cost of lives but also the harm done to both nations' economy, as well as the global economy.

Today's globalized world seems to continually shrink to a point where time and space are less and less important. Advancement and innovation in shipping allow for goods to be loaded onto ships, cross vast oceans, and then be unloaded and delivered to markets in days. Air travel, which not long ago was available only to the elite, is now affordable to all but the world's

poorest. This current era of globalization has been decades in the making. However, few argue with the notion that the end of the Cold War and East-West divide was a catalyst, speeding up the process and bringing its benefits to the world as a whole. Advancements in technology and transportation that facilitate more efficient and faster trade and travel have not exclusively benefited legitimate transnational actors but have has also benefited international criminals, terrorist, and their organizations (Rees 2006). With globalization and the barriers lifted by the end of the Cold War, the security threat has shifted somewhat from state-centric threats to transborder issues such as financial collapse and global warming, pandemics, and threats from a variety of non-state actors. The openness that globalization has created engenders an environment in which the illegal trade of drugs, arms, intellectual property rights, and money is booming and has allowed for terrorist organizations to operate globally as well (Cozine 2010).

Threat

The terrorist attacks of September 11, 2001, and the way that those responsible were able to gain entry to the United States quickly focused the spotlight on border security as a major national security concern. Advancements in technology and transportation that facilitate faster and more efficient trade and travel have not exclusively benefited legitimate transnational actors; they have also benefited international criminals, terrorists, and their organizations (Rees 2006). The September 11th hijackers were able to take advantages of flaws in the US border security and visa system to pass through ports of entry, in some cases, several times, to train, plan, and carry out the attacks.

The attacks and the way that those responsible were able to gain entry to the United States quickly focused the spotlight on border security as a major national security concern. In order to better understand how the September 11th attacks occurred, the US Congress passed legislation that created the National Commission on Terrorist Attacks Upon the United States, more commonly known as the 9/11 Commission. The Commission was tasked with preparing a full and complete account of the circumstances surrounding the September 11th terrorist attacks. It quickly became apparent to the Commission that the terrorists' ability to successfully gain entry to the United States was a key element in their ability to carry out the attacks. The topic of terrorist travel was deemed so important that it was covered in much greater detail in the form of a staff monograph separate from the Commission's final report (Cozine 2010).

The profile of those individuals who pose the greatest threat, at least in terms of terrorism, has evolved over the past decade and now focuses on homegrown violent extremism – a threat that arises from within a domestic population where citizens or residents embrace an extremist ideology and take violent action in furtherance of that ideology (Southers 2014). Much has been made of the concept of the lone wolves, inspired to carry out terrorist attacks on their own, without any specific direction from a terrorist organization. In reality, the most catastrophic attacks and sophisticated plots were carried out in some part by members of the domestic population that traveled to other areas of the world to receive training and direction from terrorist organizations. This is a phenomenon that first came to light in the aftermath of the July 7 bombings in London and most recently played out in Paris and Brussels (Cozine 2016). This threat environment has created a situation where border security and those organizations charged with securing a nation's borders now face the dual challenge of dealing with both homegrown and external threats. Traditional border security was focused on outsiders seeking to do harm – a concern that still exists today as highlighted by the June 2016 attacks at the Istanbul Airport that were carried out by attackers from Russia, Uzbekistan, and Kyrgyzstan who entered Turkey a month before the attack by illegally crossing its border with Syria carrying the suicide vests and bombs used in the attack (Karimi et al. 2016). However, there is also an internal threat of one's own citizens traveling overseas to Iraq or Syria to join terrorist organizations and possibly

return home to carry out attacks. Since 2011, nearly 40,000 fighters, including at least 6,900 from Western countries, have traveled to Syria. Around 250 of the Westerners traveled from the United States and 5,000 traveled from European Union countries. It is suspected that one third of the European fighters have returned home from Syria (House Homeland Security Committee 2016 June).

The reality is that terrorism is only one of the many man-made and natural transnational threats and challenges that face those tasked with securing a nation's borders. Today, illegal migration, human smuggling, drug trafficking, counterfeit goods, and mass migration are just a few of the man-made threats the border security officials must combat. Add to this mix a variety of natural threats such as pandemics or invasive species and the threat picture becomes even more complex. Adding to this complexity is the question of how border security agencies and organizations provide security while still facilitating legitimate trade and travel across international borders, a process vital to the health of the global economy. Nearly 1 million people and 67,000 cargo containers enter the United States each day (Custom and Border Protection 2016). Finding those individuals or items that pose a security threat among this avalanche of people and goods that cross the border each day is truly a daunting task. But the nature of borders and the strategies for securing them are as varied as the threats that are faced.

Nature of Borders and Border Security

Borders can take many forms: natural, such as rivers and other bodies of water; physical, such as walls and fences; agreed upon lines on a map; or any combination of these. How well border security and integrity are maintained directly affects those living within those borders and those who wish to profit from violating internationally accepted rules of national sovereignty. The characteristics of borders are often dictated by societal and political institutions within a particular country as well as their relationships with their neighbors and potential threats that lie just on the other side of that border (Cozine 2016).

Natural borders will often dictate a country's border security strategy. Geography has long been a barrier that has separated people into separate groups, and even today these mountains remain as a physical and political border separating China from Pakistan, India, and several other countries. The Alps have long served as an impressive physical border in Europe. The Alps have allowed for Switzerland to maintain independence political neutrality since 1291 and has not been in a state of war since 1812. This, despite the fact that during this time there has been a state of near constant hostility all around them, including two world wars. Bodies of water have also served an import physical barrier that separated people and established political borders. The English Channel has separated Great Britain from the European continent, thus allowing Britain to implement many policies separate from those of the European Union including maintaining border control between itself and the rest of the continent. The oceans, seas, and other large bodies of water remain formidable barriers. For proof, one needs to look farther than Australia and New Zealand, two large island nations that have never been invaded.

When natural barriers do not exist between countries and one country sees its neighbors or things within its neighbor's borders as threats, many countries feel the need to fortify borders with artificial barriers to prevent or limit unwanted incursions across the border. The most common artificial barrier between nations are walls. Walls are erected to prevent or deter an individual, groups of people, even foreign forces from crossing a nation's border or designed to funnel legal border crossings through checkpoints or ports of entry setup at specific locations. Walls are not the only type of artificial barriers used to fortify borders. Other types of barriers include fences, armed patrols, and air and marine patrols. Increasingly, technology is being implemented either in lieu of artificial barriers or to augment both artificial and natural barriers. These include measures such as motion sensors, thermal image cameras, and even unmanned aerial vehicles, all of which can be

monitored remotely by user who can dispatch a response team to deal with unwanted border incursions (Phelps et al. 2014).

Border security is not exclusive to the geographic location where one country meets another. Individuals and goods entering a country legally need to enter that country through a port of entry. Ports of entry are specific locations where individuals and goods can enter a country legally by land, sea, or air. They typically have a staff of people who check passports and visas and inspect luggage to assure that contraband is not imported and that individuals who are not eligible to enter a country or pose security risk are refused access. Ports of entry at international airports are usually divided up into two screening areas: passport control and baggage control. At passport control, it is individual people who are screened in terms of their eligibility to enter the country. Individuals are screened for things such as their citizenship, whether they have the required papers such as passport and visas if required, and whether there is something in the individual's background that would make them ineligible to enter the county such as previous immigration violations, criminal record, or a danger to the security of that country. When an individual is ineligible to enter a country, they might try to sneak past passport control and border security officials by presenting fraudulent travel documents to change their identity or other characteristics about them such as their citizenship. There are a variety of types of fraudulent documents that an individual can use to try and gain entry to the country that they would otherwise not be allowed to enter. These include counterfeit documents; documents that have been altered in some way, such as switching the photograph or name; using a document that belongs to an individual who looks similar to the traveler, a technique known as impostoring; or using a genuine document that is real but has been obtained by identity theft or some other illegal means. This means that officials at passport control must very quickly determine an individual's citizenship, whether they have the required documents, whether those documents are genuine, and whether the individual has anything in their background that would make them ineligible to enter the country. In recent years, many technological advances were introduced into the passenger screening process, including a variety of security features within the passport itself to aid in detecting counterfeits, radio-frequency chips that transmit information to border screening computer systems automatically, and increased use of biometrics such as fingerprint and facial recognition technology.

At baggage control, travelers' belongings are screened for prohibited items, such as drugs, counterfeit merchandise, agricultural and food products as well as insects which may pose a risk to a country's ecosystem, currency that needs to be reported, and items that require that a duty or other tax be paid. Screening at baggage control includes examining both the traveler and their baggage for prohibited items. Some common examples of how people try and sneak prohibited items through baggage control include hiding items in the lining or secret compartments of their luggage, making it look like other items such as prepackaged items and food products, sewing it into their clothing, simply strapping it on their body, or swallowing the drugs so that it passes through their digestive system after they have successfully entered through the port of entry. The only way for border officials to detect this type of smuggling is by the use of an X-ray machine. The reality is the way in which an individual can try and sneak prohibited items through baggage control is limited only by their imagination.

In addition to passengers and their baggage, many international airports also have large amounts of cargo pass through that all need to screen for prohibited items as well as cargo where duty needs to be collected. The same is true of seaports and ports of entry at land borders. At seaports, passengers and crew are screened for eligibility to enter the country, and cargo is inspected. What makes seaports somewhat different is the amount of cargo that comes in and out of seaports. One needs only to look at the enormous size of a modern container ship to have an idea of how much cargo passes through a seaport in a

given day. For example, the Triple E container ship has a capacity equivalent to 18,000 20-foot containers that would fill more than 30 trains, each a mile long and stacked two containers high (Kremer 2013). Many ports of entry at land borders have to deal with a high volume of both individuals seeking admission (i.e., pedestrians or individuals in vehicles) and large amounts of cargo carried by tractor trailers or freight trains. Adding to the challenges is the fact that these conveyances themselves can be used to smuggle both people and prohibited items through a port of entry. The number of places to conceal both items and people on a large container ship is near limitless. Hidden compartments in cars, trucks, and trains have all been used to smuggle people and goods across the border in the past. This sheer volume of cargo and people coming through a port of entry on any given day makes providing for effective border security while at the same time facilitating efficient trade and travel a daunting task.

When nature does not serve as a mechanism for border security, the characteristics of border security are often dictated not just by societal and political institutions within a particular country but also the relationships they have with their neighbors as well as potential threats that lie just on the other side of that border. For an example of how internal politics and a volatile relationship with one's neighbors impacts a country's border security strategy, one needs to look no further than the Korean Peninsula and the demilitarized zone (DMZ) that is between North and South Korea. The DMZ is a 2.5-mile-wide and 160-mile-long barrier created by both countries surrounding the military demarcation zone that serves as the border separating the two countries since the end of the Korean War in 1953 (Phelps et al. 2014). With both countries' militaries constantly patrolling their respective side of the DMZ while on alert for acts of aggression by the other side, the DMZ is the most heavily militarized border in the world with one side in a constant state of readiness to respond to threats from the other side (Phelps et al. 2014).

The nature of border security is not static and often changes over time. Perhaps no place in the world illustrates this better than Europe. Just a quarter of a century ago, what Winston Churchill famously referred to as an "Iron Curtain" divided Europe between East and West. Much like the border between North and South Korea, the Iron Curtain separated members of the North Atlantic Treaty Organization (NATO) on one side and Warsaw Pact members on the other. With the fall of communist regimes in Eastern Europe, it is now possible to drive from Spain to Finland without passing through a single border check. In reality, even before the fall of communism, the elimination of internal borders between democracies in Western Europe while at the same time strengthening their common external borders has been a goal in many European countries.

Since the 1970s, countries in Europe have worked together on an intergovernmental basis to combat cross-border threats such as terrorism, drug trafficking, and illegal migration. By 1980, the frequency of this cooperation was a growing recognition that the freedom of movement throughout the continent was a key element to establishing a common internal market; it became clear that this type of informal cooperation was no longer adequate to address cross-border issues faced on the continent (Direction Générale des Douanes et Droits Indirects 2015). Since EU member states could not reach an agreement on how to formally deal with these issues, France, Germany, and the Benelux nations agreed that the territory among their states would be without internal borders. This border-free zone became known as the Schengen Area, which was named after the town in Luxemburg where the agreement was signed on June 14, 1985. On June 19, 1990, the Schengen member states (Adopted by the Kingdom of Belgium, the Federal Republic of Germany, the French Republic, the Grand Duchy of Luxembourg, and the Kingdom of the Netherlands.) signed the Schengen Implementation Convention (SIC) to formalize their agreement on how the rules of the agreement's framework would be put into place. The convention called for the removal of checks at internal borders, common rules for crossing external borders, harmonization of entry and visa conditions,

enhancement of police and judicial cooperation, and the establishment of a common information technology system for border security. By September 1, 1993, all Schengen members had ratified the convention and the agreement officially entered into force. The Schengen Area became a reality in the spring of 1995 when, with only a few exceptions, border checks were eliminated between signatory nations and a single external border was created where members carried border inspections with identical procedures based on common rules for visa and entry requirements as well as asylum rights (European Union 2009).

During the 1990s, several other EU member states signed on to Schengen Agreement, and the Treaty of Amsterdam brought the Schengen Agreement and subsequent acquis (Schengen Convention; agreement accession to the Schengen Convention by Italy, Spain, Portugal, Greece, Austria, Denmark, Finland, and Sweden; the decisions of the Executive Committee and the Central Group; and Union acts adopted by the European Parliament and/or the Council after the Schengen acquis was integrated into Union law.) into the framework of the EU. When the treaty entered into force on May 1, 1999, every EU member state was within the Schengen Area with the exception of the United Kingdom, which includes England, Wales, Scotland, Northern Ireland, and Ireland. Schengen, along with the establishment of the euro as a common currency, became shining symbols of the reality of European integration. Ironically, today because of threats of terrorism, transnational crime, and mass migration stemming from conflicts in the Middle East and other regions, some Schengen members have reinstituted border checks on their borders, and there are political movements in some countries calling for withdrawal from the Schengen zone.

Border Security in the United States

For the latter half of the twentieth century, the continental United States was long thought to be insulated from a massive attack other than a Soviet nuclear barrage. These all changed on September 11, 2001, when its vulnerability was revealed. While September 11 brought this vulnerability to the forefront, a variety of non-state actors have long benefited from the ever-increasing openness and interconnectivity of the world to operate across national borders in violation of law and evading law enforcement to achieve their goals (Andreas 2003). However, the September 11 attacks did result in a dramatic restructuring of the United States' approach to both border security and intelligence. The Homeland Security Act of 2002 created the Department of Homeland Security (DHS) and, within it, Customs and Border Protection (CBP), which is the agency primarily responsible for border security in the United States at and between ports of entry.

Border security enforcement is the responsibility of three operational components within CBP: the Office of Field Operation, US Border Patrol, and Air and Marine Operations. The Office of Field Operations is primarily responsible for screening individuals and goods at air, sea, and land ports of entry. The US Border Patrol is the component whose main mission is to detect, interdict, and prevent individuals entering the United States illegally or smuggling people or contraband between official ports of entry. The Air and Marine Operations provides an air and maritime force to support the other two operational components by detecting, interdicting, and preventing the unlawful movement of people, illegal drugs, and other contraband toward or across the borders of the United States.

In addition to CBP, other agencies within DHS play an important role in border security: Immigration and Customs Enforcement (ICE), Citizenship and Immigration Services (CIS), and the US Coast Guard (USCG). Like CBP, ICE was created as part of DHS with the passage of the Homeland Security Act of 2002 and is the largest investigative organization within DHS by incorporating and consolidating the investigative elements of the former US Customs Service (USCS) and Immigration and Naturalization Service (INS) into one agency. ICE has two main operational components that carry out the daily enforcement and investigation activities—Enforcement and Removal Operations (ERO) and Homeland Security Investigations (HSI). ERO is primarily tasked

with interior enforcement of immigration laws including identifying, apprehending, detaining, and removing aliens residing illegally within the United States or other aliens deemed removable by an immigration judge. HSI is responsible for investigating a wide range of domestic and international activities arising from the illegal movement of people and goods into, within, and out of the United States. CIS is responsible for overseeing lawful immigration to the United States while also maintaining the integrity of the country's immigration system. The USCG is unique in a number of ways including that it is the only component of the US Armed Forces that is not housed within the Department of Defense, but rather it is part of DHS; it simultaneously acts as a military service, a law enforcement organization, and a regulatory agency. Included among the USCG's many missions are defending the United States' maritime borders by disrupting and deterring the flow of illegal drugs and undocumented migrants at sea, and preventing their entry via maritime routes to the United States.

There are also a variety of law enforcement agencies outside of the DHS that play a role in border security intelligence. Within the Department of Justice (DOJ), there are two such organizations – the Federal Bureau of Investigation (FBI) and the Drug Enforcement Administration (DEA). The FBI is involved in investigating a wide variety of issues directly related to border security, including international terrorism, human trafficking, and organized crime. The DEA's primary mission is to investigate and prepare for the prosecution of major violators of controlled substance laws operating at interstate and international levels. The Department of State's (DOS) Diplomatic Security Service (DSS) is another law enforcement agency that is directly involved with border security. In addition to its protective mission, DSS also investigates passport and visa fraud.

Conclusion

A country's border security strategy varies greatly depending on that country's geographic location, political institutions, and social and cultural heritage. For example, the border the United States shares with the Canada is the world's longest undefended border, stretching nearly 9,000 kilometers across land and water, yet there are still ports of entry and other security measures along (Phelps et al. 2014). This is in stark contrast to the borders of countries in the European Union where there are no border checks when crossing between many member states. On the other side of the spectrum is the heavily militarized border between North and South Korea. Complicating the matter further is the fact that borders and approach to border security are not static and will often change as one country's relationship with their neighbors change and events occur in that neighboring country that directly impact the security of one's own border security.

The fact is that no country can effectively go it alone when it comes to border security. In an ever more globalized world, what happens inside your neighbors' borders impacts your own. Today, the threat to security does not just come from citizens of some far-off country that follow a particular violent ideology or make a profit by exploiting a country's laws and weaknesses in border security measures to engage in illicit trade but one's own citizens traveling overseas to carry out similar activities. Another major challenge is how a country, or groups of countries, provides border security while facilitating the efficient movement of legitimate trade and travel. For border security to be effective in confronting the diverse cross-border threats faced today, cooperation is needed not just with domestic partners with border security responsibilities but also with international partners to ensure the integrity and security of their borders and the safety of their people.

Bribery

Kenneth J. Grossberger
John Jay College of Criminal Justice, New York, NY, USA

Keywords
Bribe · Criminal · Moral security

Definition

Bribery infers an "illicit exchange" in which a person or company offers a government or public official, officer, or employee valuable items, such as gifts, money, property, etc., in return for contracts, services, or other treatment (Noonan 1984).

Introduction

Bribery is often deemed illegal by society, ethically unacceptable, and judged as morally questionable due to the harm that it causes (D'Andrade 1985; Green 2005; Horder 2011; Noonan 1984). The premise of this offense is that ". . .accepting a bribe involves the violation of an implicit or explicit promise or understanding associated with one's office or role and that, therefore, accepting a bribe is always prima facie wrong" (Carson 1987, p.). Laws against bribery, that is, making bribes illegal, are tied to moral or ethical violations caused by the bribe act itself, namely, corruption. Consider the comparison of offering a free car to a politician versus a private business owner in exchange for hiring your nephew. The act is the same, but the former would be defined legally as a bribe as it violates the fair process of selecting employees for public positions; there is no similar requirement for a business owner. There are other people, due to the capacity in which they serve, such as private security guards, loss prevention employees, fire and emergency personnel, and public law enforcement to name a few, who may be offered bribes because they hold power over others, such as arsonists or criminals.

For example, a shoplifter may offer a bribe to the retail loss prevention employee who apprehended her in order to avoid arrest and prosecution. Security managers, as well as their employees, may be tempted by bribes. For instance, security personnel may be bribed to allow employees or even criminals to enter a premise to steal, or private security prison guards may accept bribes from their prisoners in exchange for a variety of privileges. Private security investigators may be bribed to not report their findings of negligence (e.g., collapsed structure or building), arson, ineptitude, etc. This entry provides an overview of the practical, legal, and moral dimensions of bribery in the context of protective security professionals and security guards.

The Cultural Aspects of Bribery

Noonan (1984) stated that while a lack of admission was common, and the deceit inherent, the behavior was pervasive as it occurred in almost every society and in every era. Yet despite its negative connotations, bribery has been rationalized in the following ways:

1. "Everybody does it." Noonan has shown bribery occurred in numerous eras and societies indicating the pervasiveness of illicit exchanges.
2. "It is necessary to do it." This reasoning implies it was done for job survival or to gain acceptance in a given situation.
3. "Reciprocities are formally indistinguishable." This argument relies on a slippery slope premise in that many types of bribery seemed to be non-corrupt exchanges.
4. "It is immorally enforced." Noonan referred to the inconsistencies inherent in the hypocritical ways the rules against bribery were only sometimes enforced or where bribery was situationally or cultural mandated. For example, if it was routine that employees steal goods from a warehouse, and the security guard is invited to join in, then the guard is corrupted and the behavior is reinforced.
5. "The material effect . . .is either trivial or undemonstrated." This argument essentially suggests that no real harm is done and that bribery in many cases amounts to no more than a societal "taboo." This moral logic is the same as arguing that pilfering really is not stealing and is a victimless crime (such small-scale shoplifting in retail stores, especially when the loss prevention security guard looks the other way in return for some of the stolen goods).

Noonan (1984) contended that, whatever the rationalization, the future of the bribe remains problematic, because, despite the level of relative unacceptability, the act itself is "universally shameful," is a "betrayal of trust," and contravenes a "divine paradigm." He stated that "bribery is a legal concept," thus, the punishment comes from the law, but enforceability is an issue and enforcement of the law remains selective in that the proscription of such illegal reciprocity depends on accepted cultural norms and contextual notions. While bribery itself is "criminal and consensual," the motivations are often dissonant and personal.

Bribery, Security Personnel, and Insurance

Security personnel protect residences, commercial office buildings, institutions (schools, hospitals, nursing homes), government buildings, retail stores, warehouses, and airports, to name a few. Security guards may be bribed for access to such premises (when the officer's post responsibility is access control), to look the other way when someone engages in wrongdoing, and to abet theft. Payments can be in cash, a share of the stolen merchandise, or sex, favors, or food. A key factor is that security guards are typically low paid, which makes them vulnerable, and thus the risk is enhanced. The act of bribery is usually considered a crime (see ► "Investigations: Criminal"), based on criminal justice theory, which states that a crime has three elements: the mens rea (criminal

intent; intent to coerce decision or action), the actus reus (the criminal act itself, offering or taking of something of value in exchange for bribed acting, promising to act within his/her capacity or duties to provide briber with a benefit, including going unpunished for breaking the law), and the facts of the case (Stein 2012).

Security guards may be natural targets for bribes (see ▶ "Retail Security: Use of Security Guards"). For example, can private security guards legally perform searches? There are different rules for searches in the private sector. Security guards cannot use "reasonable suspicion" as a cause for a search as that is the province of law enforcement under the US Supreme Court ruling in *Terry v. Ohio* (Cornell Law School n.d.). Security guards must have probable cause (a high standard of evidence) to make a stop, which means the security guard must see the act (see ▶ "Retail Security: Use of Security Guards"). However, in retail, for example, a security guard working loss prevention in stores may check a shopper's bags, if it is a store policy to do so (and the guard's post orders permit it), but then only with the permission of the shopper. But if the guard sees the shopper take something, and then try to leave, the officer may stop the shopper and call the police.

This is a classic opportunity for a shoplifter to offer a guard something in return for being released. The guard's training should take effect, and if not, then the potential for a bribe will increase. If the guard stops the shopper (or takes him/her into custody), then the guard might be accused of illegal restraint. As security guards are not police officers, they are not protected by various "shield" laws which insulate police personally from civil suit. Under citizen's arrest laws, the guard may make the stop but must be sure or may be subject to arrest and lawsuit herself. Thus, a security guard, like any other citizen, may arrest another person without a warrant but subject to certain limitations (Wollan 2016).

Security guard companies typically have general liability insurance, which provides protection against most causes of action involving physical security (see ▶ "Security: Contract"). Many companies also have Employers Practices Liability Insurance (EPLI) which protects companies from so-called third-party actions or discrimination cases. If a private undercover agent or a store detective is accused of bribery, the defendant's lawyer might threaten a third-party action to induce the company to drop any criminal charges. Lawsuits that result therefrom can be costly. Security companies may buy crime bonds, which protect companies against such events as employee dishonesty and "mysterious disappearance," where items are missing without explanation while guards are on duty. Many such cases are the results of the guard being bribed to assist in the theft. General liability, third-party insurance, bonds, and other forms of protection can be expensive and are major concern in private industry. Most lawsuits are settled prior to trial, but the effect on the defendant company's loss run (the record of losses in an insurance policy) can prove to be quite expensive. The legal and reputational damage to the security guard may be serious and result in banishment from the security industry in that jurisdiction.

Security guards perform basic functions: observe and report, and post and patrol. Thus, they are responsible for basic security (perimeter patrol, access control, protection of assets, and reporting theft and dangerous conditions). But corrupt officers endanger the very people and assets they are hired to protect. This is especially so for critical assets in such facilities as hospitals, nuclear power plants, banks, homeless shelters, museums, law offices, and government offices. Corrupt guards that fail to protect these assets and the people therein, by accepting bribes do not do their jobs, violate the basic precepts of their position, invert their purpose, and abuse the trust given to them. The potential damage done by a security guard who accepts a bribe to allow access by the wrong people, allows theft and vandalism, and looks the other way when crimes are committed, or partakes in such crime, could be severe or even catastrophic. Thus, the risk posed by the bribery of a security officer ranges to the extreme and is a highly significant issue for the industry.

The Morality of Bribery

D'Andrade (1985) declared flatly that "bribery is wrong" and is "immoral almost by definition in the same way that murder is." However, Horder (2011) suggests that the criminality of bribery "is surprisingly difficult to explain" when considering the "harm-doing" of the act, because some bribes cause no apparent harm. Horder contends that the criminal justification for bribery relies on the "nature and degree of remote harm" potentially resulting from a bribe resulting in no sanction. If there is no punishment, then there would be no deterrence, but as deterrence is difficult to measure, this results in a "potentially problematic case" for determining such a criminal act. Private security agents are no less susceptible to such deterrence, but if punishment is not certain, then the deterrent effect would be difficult to measure (Paternoster 2010).

Green (2005) characterizes bribery as a "bilateral agreement between 2 parties" wherein "the briber gives or offers something of value in exchange for the bribee's agreeing to act on the briber's behalf." The person bribed transgresses against a duty to his or her position, and the briber "commits the morally wrongful act" by corrupting the bribee. Security personnel are often disadvantaged in such a way, and as they are licensed by the government in most states, they are liable to be prosecuted for certain forms of bribery (such as transactions that involve criminal acts on a client's property) and possible loss of their licenses.

Conclusion

Bribery is leverage. It is the result of an exchange between two or more parties, such that each needs something from the other. The lever is the thing to be exchanged, desired by the bribee (the person or entity accepting the bribe) and offered by the briber (the person or entity doing the bribing), in return for something of value desired by the briber. This basic process holds true for the bribe at its many levels, including security. Those working in security are in positions of trust, guard people and assets, and are therefore targets for those who seek to profit from the venue protected by private security professionals. The opportunity and risk for bribery are ever present and must be guarded against.

Bus Security

Dorothy Moses Schulz
Law, Police Science, and Criminal Justice Administration, John Jay College of Criminal Justice (CUNY), New York, NY, USA

Keywords

Crime Prevention Through Environmental Design (CPTED) · Closed circuit video surveillance (CCTV) · Operator assaults

Definition

Bus (motor coach) security is comprised of the procedures and activities to protect equipment, facilities, employees, and patrons of bus companies from harm; it includes efforts to prevent, mitigate, respond to, and recover from incidents that may occur on vehicles, at terminals and waiting areas, or others areas for which bus companies are responsible.

Introduction

Assessing security needs and responses of bus systems is challenged by the large number and types of bus systems operating in North America. Security for buses has received less attention than for other transit modes (such as air or rail travel). With few exceptions, bus security is less focused on violent and terrorist-related crimes than on public order offenses in stations, waiting rooms, and on vehicles, and with crimes against the transit system itself such as vandalism, theft of fares, assaults on bus operators, and sometimes vehicle hijackings (Bus Safety Data Report 2018). Also, because bus systems are unlikely to have their own police departments, serious crimes are reported to the local police and nonserious security events (i.e., fare evasion or patron fights that do not result in injury) often go unreported (Schulz and Gilbert 2011).

Most people define a "bus" simply as a vehicle that runs on streets and picks up and discharges passengers; however, within the transit industry, bus systems vary by type of service (local, commuter, long-distance, or school) and whether they are public or private (Fact Book 2017). Local bus service involves travel within a city or county on fixed-routes (the same route and stops on all trips); demand-response (vans arrive when called to take a patron to a specific destination), and commuter buses, which primarily connect suburban areas with the central business district. These are overseen in the United States by the Federal Transit Administration (FTA), part of the Department of Transportation (USDOT), and in Canada by Transport Canada (TC). There are also hundreds of long-distance (also called intercity) bus systems; among the best known are Greyhound, Trailways Lines, and Peter Pan, which serve about 4,000 communities in the United States (Walsh 2003). Leisure and charter buses are considered intercity carriers. In the United States, the Federal Motor Carrier Safety Administration (FMCSA), part of USDOT, and in Canada, TC, together with the provincial governments, regulate these buses. School buses, which may be used only to transport students to/from school or for school-related activities, are regulated in the United States by the National Highway Traffic Safety Administration (NHTSA), also part of USDOT, and in Canada by TC.

The American Public Transportation Association (APTA) estimates that not including school and intercity buses, buses operate over 230,000 miles of streets and roads in the United States and in 2014 employed about 300,000 people (Fact Book 2017). TC estimates that 15,000 buses are operated in Canada by about 1,500 different providers employing about 9,000 people, primarily as drivers (Road Transport n.d.; CUPE Fact Sheet 2017). No central repository of

crime data exists in either country. In the United States, the FTA maintains a National Transit Database (NTD), but greater emphasis is placed on safety than on security and reporting is not mandatory. Despite the industry fragmentation, government reports, agency documents, and media coverage have highlighted common security problems and solutions among bus systems. This entry describes security issues facing North American bus systems and discusses crime prevention interventions and strategies employed by most of them to counter criminal activity.

Crime Prevention Through Environmental Design (CPTED), Closed Circuit Video Surveillance (CCTV), and Communications Enhancements

Beginning in the 1970s and intensifying in the 1980s and 1990s, transit systems recognized crime and public order problems, including loitering by nonpatrons, homeless persons, and unruly teenagers; fare payment evaders who harassed bus operators and other patrons; and graffiti on the equipment, in stations, and on bus shelters. To counter disorder, agencies adopted crime prevention though environmental design (CPTED) principles, such as improving lighting in yards and public facilities, adding fencing to bus garages, and installing electronic closed circuit video surveillance (CCTV) to monitor their property (Schulz and Gilbert 2011).

In stations, bus systems rearranged furnishing to minimize hiding places, and to curtail loitering they installed slanted seat or separated benches to prevent stretching out across three or four seats. Keeping bus transfer points and buses clean became a priority as did preventing graffiti or scratchiti (etching rather than spray painting onto surfaces). Small systems, with small security budgets, discovered that playing classical or other soothing music deterred rowdy teenagers, whose noise and boisterousness often frightened other patrons, particularly the elderly, from frequenting the stations. System operators often have little control over on-street bus shelters, since most are not responsible for their care or cleanliness, but many have worked with local jurisdictions to enhance housekeeping in and around shelters and to minimize advertising and other signage that blocks benches from view (Schulz and Gilbert 2011).

Other countermeasures include public awareness campaigns; increased patrols by law enforcement or security personnel; legislative efforts to increase penalties for assaults on drivers; and technological solutions, particularly CCTV and devices that allow operators to report suspicious or dangerous behavior without alerting the perpetrator or other passengers (Tools and Strategies 2018). Bus systems rely heavily on CCTV onboard vehicles, in large stations and transportation centers, in parking facilities, and in bus garages. Between 2001 and 2015, the percentage of buses equipped with CCTV increased from 13% to 73% (Fact Book 2017). Interior cameras (in the buses facing patrons) are generally publicized by signage to enhance patron security by deterring criminal behavior although the video is also used to support or refute accident or injury insurance claims (Tools and Strategies 2018). External cameras (facing outside the bus) may record patrons sneaking onboard without paying but are used primarily to investigate accidents.

Other security enhancements are intended to increase communication between a bus operator and a central command center and between a bus operator and patrons. For instance, providing operators with two-way radios allows them to report when they need supervisory or police intervention. Automatic vehicle location (AVL) equipment, similar to a global position system (GPS) but tied to a particular vehicle, allows agencies to know immediately if buses have left their assigned route. Tracking a bus that has reported a security problem makes it easier for police to develop response strategies (Schulz and Gilbert 2011; Tools and Strategies 2018). In addition to security, AVL can also provide information to passengers waiting for vehicles.

Public address systems, automated stop announcements, and passenger-operator intercoms also serve a dual purpose of keeping passengers informed and increasing the security of the trip (Schulz and Gilbert 2011; Tools and Strategies 2018). Many systems have programed

their exterior destination signs to flash "Call 911" upon operator activation. If the operator cannot safely communicate with a command center, it is anticipated that someone on the street or roadway will inform the police that the bus is in trouble.

Industry associations are active in developing security strategies. Together with the American Association of State Highway and Transportation Officials (AASHTO), APTA, and the Community Transportation Association of America (CTAA), the FTA administers a voluntary safety and security program that offers audits by expert practitioners and checklists that can be used to evaluate safety, security, and emergency preparedness programs; publishes best practices, and sponsors conferences and seminars. In Canada, TC collaborates with bus operators, the Canadian Urban Transit Association (CUTA), and Motor Coach Canada (MCC) to develop information on risk assessments; employee training; exercises and drills; writing and maintaining security plans, and creating public awareness campaigns (Road Transport n.d.).

Fare Policies, Fare Evasion, and Operator Assaults

Most violent crime on buses in the United States and Canada stems from fare evasion or transfer policies, which result not only in lost revenue but in assaults on bus operators who challenge patrons refusing to pay their fares (Bus Drivers under Attack n.d.). To minimize these thefts and arguments, many systems accept only exact or prepaid fares, with no cash accepted on the vehicle. Systems have found that a single fare for an entire trip, rather than zoned fares that depend on distance, minimize driver/patron disputes (Stern 1997; Larwin and Koprowski 2012). Many buses operate with proof-of-payment systems that allow patrons to board without showing a ticket but who may be asked to show it to fare enforcement officers who board the vehicles periodically to make such checks. Enforcement officers are generally authorized to ask patrons to exit the bus if they have no ticket or, if the enforcement agents' handheld computer indicates a repeat offender, to issue a citation for fare evasion (Schulz and Gilbert 2011; Larwin and Koprowski 2012).

Attacks on operators have been the impetus for the installation of cameras on buses and of driver safety partitions. For example, New York City began installing cameras in 2011 in response to a 20% spike in operator assaults compared to the previous year. Earlier, in 2008, a driver was killed after refusing a nonpaying patron a free transfer, leading operators to more actively report victimizations (Permino 2012). Similarly, the Los Angeles Metro bus system added surveillance equipment and plastic barriers separating drivers from patrons in 2015 after a 35% increase in driver assaults between 2012 and 2015, including 138 assaults in 2014, a third of which began as fare disputes (Metro to Raise Security. . . 2015).

Transit systems and unions representing drivers have been successful in lobbying states to increase criminal penalties for assaults on operators. According to the Amalgamated Transit Union (ATU), which represents about 200,000 members in 45 states and nine Canadian provinces, 30 states have enacted such legislation (Bus Drivers under Attack n.d.). Riders in many cities are familiar with signs reminding them that assaulting a bus driver is a felony.

Bus crimes not involving operators are similar to crimes occurring in other public space. They range from violence involving passengers to violence that starts on the street but carries over into the bus. An example of the latter was a dispute near a Honolulu, Hawaii, bus stop in March 2015 that led a group of individuals to ask a driver to help them escape from a reportedly armed group chasing them. The driver permitted them to enter the bus, but when he denied entry to the second group, they attacked the bus, shattering windows and the windshield (Driver Hailed as Hero. . .2015). While these incidents receive local media attention and are highlighted by unions representing operators and by rider advocate groups, estimating how often they occur is virtually impossible.

Hijackings

Bus hijackings of local public buses, long-distance private buses, and school buses are rare.

Because of each one's unique circumstances, they are difficult to classify or prevent. Many result from riders' behavioral or psychological problems. For example, an intercity bus hijacking at John F. Kennedy airport in 1977 which resulted in two passengers being killed and two wounded, involved a gunman who told police he was "fed up with society" before being taken into custody after a 13-hour standoff (Bus hijacker kills 2… 2017). In 2012, a drunken patron who hijacked a Greyhound bus traveling from Washington, DC, to Miami, was sentenced to more than 19 years in prison after pulling a pellet gun on the driver and demanding to get off the bus. Here, after the hijacker threatened other passengers, the driver complied with instructions to allow them to exit the bus. When the hijacker allowed the driver to also exit to use a gas station restroom, law enforcement personnel surrounded the bus and subdued him (Rockwell 2012).

A number of hijackings of occupied school buses have received vast media attention due to what effectively becomes the kidnapping of young children. An early case that received much notoriety occurred in July 1976, when 26 children between the ages of 5 and 14 and their bus driver were kidnapped in Chowchilla, CA, by armed men blocking the bus's route. The students, who were attending an elementary school summer session, were being dropped off on their way back from a field trip. The kidnappers hid the bus and drove the children and their driver around in two vans for almost 12-hour before taking them to a quarry, from which the driver and the children ultimately escaped. Although the three kidnappers, who were all caught, tried, and sentenced to life in prison, had attempted to make ransom calls, they were unable to do so because the local telephone lines to the police were tied up by media calls and families searching for their children. The arrests were a result of the bus driver, under hypnosis, remembering the license plate number of one of the vans (Lindsey 1976; Baugh 1979). The incident was the basis of a number of television programs, including in 1993 an ABC Network 2-hour special, *They've Taken Our Children* (2019) and in 2015 on the cable network Investigation Discovery (*House of Horrors: Kidnapped*). The case received renewed media attention in 2016, when a lawsuit was filed on behalf of the victims after two of the three kidnappers were paroled, one in 2013 and another in 2015 (Chowchilla school bus… 2016). Another case involved an armed school bus driver who took 13 children from rural Pennsylvania on an unauthorized 6-hour, 115-mile "field trip." None of the children was physically harmed, and although many indicated they were frightened, at least one was quoted as saying "we were having fun." During arraignment, it was determined that the driver had been treated for psychiatric problems and had recently stopped taking his medication (Court Orders Psychiatric…2002; Bus Driver Faces…2015).

The randomness of these events contributes to the difficulty preventing them. For instance, in 2013, a knife-wielding man hijacked 11 elementary-school-age children and their bus driver. With no apparent motive, after a woman had denied his demand outside an apartment complex to be given a vehicle, he jumped onto the bus. Although armed with a knife, he made no threats against the driver or the children. After a chase by local police, he was removed from the vehicle and charged with vehicle piracy, kidnapping, and aggravated assault (Huynh and Lesnick 2013). In another case, in 2018, near Fresno, CA, a man hopped onto a bus carrying more than 40 elementary school children when the driver stopped so students could use a restroom. While a teacher escorted two students to the restroom, the assailant jumped onto the bus and tried to yank the driver from her seat but she removed the keys from the ignition and hid them. Although the hijacker had previously been charged with attempted carjacking and attempted kidnapping, based on his statements, police authorities believed that might have had mental health issues (Darrah 2018).

Hijackings sometimes involve former or want-to-be employees; in New York City, in 2016, a former bus driver took a vehicle for a "joyride" after being asked not to smoke on a bus. Also in the New York area, Darius McCollum, who suffers from Asperger syndrome, has posed as a subway motorman or bus driver to take over

New York subway and buses, New Jersey Transit buses, and Greyhound buses at least 30 times, resulting in his being incarcerated 19 times. Despite no one being harmed by McCollum, the ease with which he has entered garages or unattended equipment raises questions about the success of existing security measures (*Off the Rails* 2016).

Terrorist Activity

Discussions of terrorist activity at mass transit generally do not separate buses from rail and do not clearly distinguish between domestic and international events. Terrorist actions against buses occur frequently in Israel, India, Pakistan, and the Russian Federation. The Mineta Transportation Institute (MTI) Database on Terrorist and Serious Criminal Attacks Against Public Surface Transportation counted over 3,000 attacks against public transportation between January 1, 1970 and January 23, 2012. Of these, 47.4% were against buses, bus stations, and bus stops (Butterworth et al. 2012, p. 3), but none were in the United States or Canada. A more recent account of terrorist activity targeting US transportation systems between 1970 and 2015 counted 89 attacks; none involving buses (Miller 2016). Two recent incidents also illustrate problems in defining a terrorist-related event and the actual target.

In New York City, in December 2017, an explosion occurred in a passageway connecting the Times Square subway station with the Port of New York and New Jersey's (PANYNJ) Bus Terminal at Eighth Avenue and 42nd Street during the morning rush hour. The suspect, who, according to police, acted on behalf of the Islamic State, was convicted 11 months later; it was never clear whether he was targeting the subways, the bus system, either, or both (Weiser and Palmer 2018). In January 2018, a Mexican national in the U.S. illegally, who was on a Greyhound bus traveling through the Midwest threatened to kill law enforcement personnel. Although he was charged with making terrorist threats because he mentioned law enforcement, it is unclear whether this was actually a terrorism-related incident (Fox6news 2018).

Despite the dearth of terrorist-related threats to buses, an Intercity Bus Security Grant Program (IBSGP) established by the 9/11 Commission Act of 2007 and administered by the Federal Emergency Management Agency (FEMA) provides funds for anti-terrorism activities. The 2015 and 2016 funding was $ 3 million; for 2017 and 2018, it was reduced to $ 2 million. After meeting the Department of Homeland Security (DHS) requirements, systems may apply for funds to upgrade physical security at bus stations and maintenance facilities and for airport-like passenger and baggage screening. Critics of IBSGP note that it has never been fully funded and that funds are disbursed only to agencies that have demonstrated to FEMA that they have credible security plans and will use the funds to advance a specific security program (Burtwistle 2017).

The Transportation Security Administration (TSA) funds bus anti-terrorist training programs for employees, especially drivers, and periodically works with bus systems to set up security checkpoints in stations. With the exception of some intercity buses, screening of bus and rail patrons on a regular basis has not been successful. These travelers expect quick entry and exit from the coaches and to carry their luggage onto the vehicle or place it nearby. Even if such measures were in place, they would not prevent external attacks such as bombs placed in the road, carried in vehicles traveling adjacent to the bus routes or rail lines, or hijackings.

Drug Interdiction and Immigration Enforcement on Buses

Controversy surrounds police officers' authority under the Fourth Amendment to search and seize contraband on public buses. Early activity and Supreme Court cases in this area were centered on drug interdiction but the authority has been used more recently for immigration checks on passengers. Inconsistent drug-related decisions led ultimately to the *U.S. v. Drayton* (122 US

2105, 2002), which involved two drug seizures from two individuals on the same bus. The Court ruled that officers are not required by the Fourth Amendment to "advise bus passengers of their right not to cooperate and to refuse consent to search" (*Drayton* 2002, p. 2107). The decision has been the basis for Customs and Border Patrol (CBP) agents to board buses to check patrons' immigration status. The checks, primarily on intercity buses and sometimes on local public buses, generally result in those being taken into custody being turned over to Immigration and Customs Enforcement (ICE) for detention and possible deportation. Although a coalition of groups led by the American Civil Liberties Union (ACLU) has demanded that Greyhound stop immigration enforcement, the company says it has no choice, that it does not cooperate with CBP agents, and that the searches have negatively impacted both its customers and its operations (Hayoun 2018).

Conclusion

Measuring the number and type of security incidents on buses is impossible due to decentralized reporting systems and the different responses by operators and local jurisdictions. Although FTA's NTD captures some data, its definition of a "security event" as one "where a person causes harm to themselves, or another person or damage to property, including suicides, assaults, and bomb threats" (Bus Safety Data Report 2018) differs from law enforcement definitions. In addition, because many bus systems do not report to NTD, it is difficult to interpret the data as reflective of trends in security incidents occurring on buses. Despite these difficulties, bus systems have been and continue enhancing security for equipment, operators, and patrons primarily through CPTED, CCTV, and other technological means.

Business Continuity Plan

Malcolm B. Reid
College of Graduate and Continuing Studies, Norwich University, Northfield, VT, USA

Keywords
Business continuity management (BCM) · Business continuity plan (BCP) · Business impact analysis

Definition

ISO 22301 defines the business continuity plan as "documented procedures that guide organizations to respond, recover, resume, and restore to a predefined level of operation following disruption."

Introduction

Business continuity is the practice of preplanning for disruptive events that could negatively impact an organization and its stakeholders. It provides a framework for timely recovery of operations following a disruption that minimizes the negative impacts. Business continuity planning (BCP) is similar to Continuity of Operations Planning (COOP). COOP is used in the public sector for continuity of government whereas BCP is generally used by the private sector. According to NFPA (2019) "the most significant difference between BCP and COOP lies with objectives and the definition of critical or essential functions and how demand for public sector essential services could change during an incident". The business continuity plan provides a playbook designed to guide action in the event of a disruption.

All organizations should develop, maintain, and exercise their business continuity plan. The process of business continuity planning begins with analysis which includes the business impact analysis and risk assessment. The BIA identifies and prioritizes critical functions, while the risk assessment identifies and prioritizes likely threats

Business Continuity Plan, Fig. 1 Process for BCP development and improvement

to those critical functions. Business continuity strategies and BCPs are documented based on the analysis outputs. Documented plans must be validated and rehearsed through exercising to be reliable. Lessons learned from actual events and exercises can be used to update plans for continual improvement (Fig. 1).

Business Impact Analysis

The business impact analysis (BIA) provides essential information for developing the business continuity plan. The BIA assesses impacts of a disruption on an organization including consideration of potential damage to reputation, market share, operational effectiveness, or stakeholder relationships along with resource requirements to continue or recover from a disruption (NFPA 2019). Resource requirements that should be considered include "Personnel, Equipment, Infrastructure, Technology, Information, and Supply Chain" (NFPA 2019).

The BIA also determines timelines for recovery including the Maximum Tolerable Period of Disruption (MTPD), the Recovery Time Objective (RTO), and the Recovery Point Objective (RPO). The MTPD is defined by ISO 22301 as the "time it would take for adverse impacts, which might arise as a result of not providing a product/service or performing an activity, to become unacceptable." MTPD is also referred to as the Maximum Tolerable Outage or Maximum Acceptable Outage. The RTO is the targeted time for recovery of the product, service, activity, or resource which should be less than the MTPD to avoid unacceptable impacts (ISO 22301). The RPO identifies the maximum data loss and the point to information should be restored to in order for activities to operate following a disaster (ISO 22301).

In addition to evaluating the impacts of a disruption over time, the BIA identifies essential supporting business processes and dependencies for each critical function. Interdependencies of processes are also considered. The primary categories of dependencies are:

- Workforce – Skills and minimum number personnel to execute BCP procedures.
- Facilities – Buildings including office space, data centers, or manufacturing space.
- IT infrastructure – Servers and their configuration requirements, networking dependencies, this may include Cloud-based solutions.
- Data – Information backup requirements to support the critical functions (paper, data, backup arrangements, security and storage requirements).
- Third party providers – Any critical dependencies provided by third parties must be identified.

Based on information gathered in the BIA, business continuity plans are designed to achieve the RTO and RPO with consideration for the resource requirements and organizational constraints. This approach enables an organization to effectively balance the cost and effectiveness of continuity strategies while mitigating unacceptable impacts.

The risk assessment complements the BIA by identifying threats and risks associated with the prioritized activities and resource requirements. The risk assessment also identifies Single Points of Failure (SPOFs) through following process flow and dependencies to map (Bryant 2013).

Based on findings from the risk assessment, the continuity strategy identifies measures that will reduce likelihood and impact of prioritized likely threats to critical functions.

Business Continuity Strategy

The plan should include a continuity strategy that meets the requirements identified in the business impact analysis. The strategy is the overall approach to continuity and recovery. Strategies address loss of critical resources identified in the BIA. Strategy is selected based on its ability to achieve the RTO and RPO and in alignment with the organization's resource capability. Strategies that deliver the greatest resilience and speediest recovery are often the most expensive unless they are aligned with business as usual ways of working. Table 1 outlines common strategies.

There are additional strategies and variations of these strategies which can be adapted to the organization's specific requirements.

Roles and Responsibilities

The incident response structure provides a management structure and procedures for response to disruptions. According to the BCI (2018), the response structure provides "established command, control and communication systems to ensure that the organization has a clearly documented and well understood mechanism for responding to an incident, regardless of its cause." The response structure activates the business continuity response in accordance with established processes and procedures for "activation, operation, coordination, and communication of the response" (ISO22301). The response structure should align with the organization's normal organizational structure.

Responsibilities include communication, coordination, and specific actions that must be carried out to facilitate the recovery. The Incident Command System (ICS) model has been widely adopted for development of an incident response structure. The ICS was developed to provide a common organizational structure covering all functions required for effective emergency response (Bigley and Roberts 2001).

Internal and external communications are particularly critical roles in the business continuity response. Internal communication involves keeping the workforce up-to-date on the disruption and business continuity response and their expected actions. External communication is directed at stakeholders and the media.

Business Continuity Plan, Table 1 Business continuity plan recovery strategies

Strategy	Addresses loss of	Examples	Relevant disruption scenarios
Remote working/ telework	Location	Employees work from home or other locations by connecting to the Internet to access corporate resources usually via VPN	Physical disruptions at primary facilities where application dependencies are not impacted Not effective against cyber attacks or people disruptions such as pandemics
Process transfer	Location and people	Organizations that carryout processes at multiple locations can shift work to another location if the capacity is available or can be increased for the duration of the disruption	Physical disruptions where local internet connectivity is not available or local people disruptions
Alternate location	Location	Employees relocate to another location not impacted by the disruption. Organizations with multiple locations may be able to leverage their additional facilities. Organizations may also engage third-party providers who specialize in providing hot or warm standby sites equipped with relevant working requirements	Physical disruptions including natural disasters

Plan Documentation

The first priority in a business continuity plan is the health and safety of personnel.

The plan provides documented procedures for response to a disruption and how the organization will continue or recover within the agreed RTO. The plan is a playbook for the individuals and teams with identified roles and responsibilities in the continuity and recovery. Once the plan has been documented, it must be communicated to relevant parties particularly all individuals with roles and responsibilities defined within the plan. Plans should be available for reference in an actual disruption either in hard copy or electronically.

The BCI (2018) recommends that plans should be direct, adaptable, concise, and relevant to make them focused and user-friendly in high pressure disruptions.

Phases of business continuity guided by the plan include:

1. Activation
2. Execution

Plans may also cover the reconstitution phase to guide return to normal operations. This includes procedures to return to business as usual after the disruption has concluded.

The plans should document assumptions, roles and responsibilities, escalation and delegation processes, and liaisons for external organizations (NFPA). According to ISO 22301 (ISO 2012) and ASIS BCM, "Each plan shall define purpose and scope, objectives, activation criteria and procedures, implementation procedures, roles, responsibilities, and authorities, communication requirements and procedures, internal and external interdependencies and interactions, resource requirements, and information flow and documentation processes."

Recovery Procedures

(a) Sequence of activities for overall coordination and management of the disruption based on priorities
(b) Specific actions that must be taken to meet the recovery time objective
(c) Escalation/awareness

Contact details for all personnel with roles and responsibilities in the plan should be included and kept up-to-date regularly.

Additional information that may be included in your plan includes:

- Site maps for facilities
- IT architecture diagrams
- Special instructions for recovery tools

Research findings of a study conducted on BCP implementation identified the most effective aspects of the plans as "identification of critical functions, communications plan, information back-ups, and training and testing" (Hatton et al. 2016).

The plan is sometimes called a playbook because it provides the team with guidance on actions to take in a disruption. The level of detail required for the plan depends on the complexity of procedures that must be carried out.

Plan Activation/Exercising

Once the plan is documented, recovery teams must be prepared for plan activation. Exercising is the best way to prepare teams for an actual disruption and invocation of the plans. The business continuity procedures require exercising to provide all team members with recovery roles and responsibilities, an opportunity to practice their response, validate plans, and identify improvements. In addition to validation of plans, exercises can also provide capacity testing and awareness for internal and external stakeholders (ASIS BCM).

Procedures for plan activation should be included in the business continuity plan under the section on "activation criteria and procedures." Activation procedures should clearly state the authorized decision makers and conditions and are required to invoke the business continuity plan. The procedures should define disruption thresholds that guide activation of the plan. The impact thresholds which guide decision makers in invocation of the plan should align with the organization's priorities and business

continuity requirements such as number of customers impacted or length of the disruption in hours or days impacting prioritized activities and critical dependencies (BCI 2018). The activation procedures should include a process for assessing the actual impact of the disruption on "people, property, operations, or the environment" (NFPA 2019). Documenting clear guidelines for activation supports sense making in potentially stressful situations where decision making can be degraded. Well before the disruption occurs, "staff must be given frameworks that they can use to correctly interpret what they see and experience when things go wrong" (Oberlin 2017).

An emergency operations center (EOC) is established on activation of the business continuity plan to maintain communications and coordination with incident command (NFPA 2019). The EOC may be established in a physical meeting room or using virtual meeting solutions. The EOC remains in operation for the duration of the disruption. In a disruption, collaboration is required for an effective response. The EOC is primarily responsible for maintaining coordination. Collaborative exercises with the EOC activated are recommended to improve communication and coordination between teams.

Exercises and tests provide an opportunity for individuals and teams to practice their business continuity roles and responsibilities including coordination while also assessing plan effectiveness. There are several different approaches to exercising beginning with discussion-based exercises and culminating in full scale rehearsal exercises. Exercise objectives are defined for each exercise during exercise planning to clarify aims and expectations.

Expected outcomes linked to core capabilities are identified in the exercise objectives. The exercise structure and scenario should facilitate achievement of the objectives. Evaluation of the exercise is based on performance of the participants in respect to the exercise objectives. Directly following the exercise, a debriefing is conducted to capture participant impressions and recommendations.

An exercise report is compiled to document the exercise evaluation and capture lessons learned shared in the debrief and evaluation. Similarly, after an actual event a review of the recovery is conducted to identify gaps in capabilities, or plan procedures and make recommendations for improvement. A program of continuous improvement is required to deliver plans that can work in an actual disruption. Lessons learned are captured following an actual incident or exercise. Action plans for improvement are developed based on lessons learned.

Conclusion

Business continuity facilitates recovery from a variety of threats both intentional and unintentional. An all-hazards approach is recommended which focuses on response to disruptions of critical resources and therefore can be adapted to any scenario including natural disasters, structural failures, human errors, and cyber-attacks. BCP priorities should be aligned with the organization's strategic priorities including customer/stakeholder requirements, legal and regulatory requirements, and organizational policy.

Celebrity Protection

Robert Matthiessen
Security, Fire, and Emergency Management, John Jay College of Criminal Justice, City University of New York, New York, NY, USA

Keywords
Close protection · Motorcade and Route Management

Definition

Celebrity protection is the protection of a human asset against harassment, injury, death, and embarrassment.

Introduction

When analyzing celebrity protection, some would argue that it is the same as executive protection, which are all part of the principles and fundamentals of close protection security. There are many variations in the close protection field when it comes to protecting the human asset. As mentioned, the fundamentals and principles remain the same if you are going to ensure an effective protection strategy. However, one difference between providing executive compared to celebrity protection security is the latter's public exposure, but there are other differences between the two.

When analyzing executive protection in comparison with celebrity protection, it should be noted that executives are more reserved and unwilling to engage in extensive public interaction compared to their celebrity counterparts. Most executives are corporate leaders responsible for making important decisions for the company and their shareholders. Their unnecessary exposure can result in danger by an unsuspecting individual. Since there is no immediate need for unnecessary public exposure, executives are primarily shielded from this level of threat. The executive protection professional would advise against unnecessary or high-risk exposure when it is not necessary, and for the most part, the executive usually complies. On the contrary, celebrities for the most part are dependent on their fan base and are more willing to interact and be seen and photographed in public (Holder and Hawley 1998).

This entry will identify celebrity security as the *close protection professional* (*CPP*). If you look at various videos and news reports, celebrities are the most exposed and accessible people in a close protection environment. The ability to navigate crowds and paparazzi in a public space can be very demanding, if not dangerous, for both the celebrity and the CPP. The ability of the CPP to protect a celebrity from harm and/or embarrassment will depend on the training and experience of the CPP to perceive danger, react quickly, but

© Springer Nature Switzerland AG 2021
L. R. Shapiro, M.-H. Maras (eds.), *Encyclopedia of Security and Emergency Management*,
https://doi.org/10.1007/978-3-319-70488-3

also to remain rational and professional at all times. When celebrities are seen in public, they are usually surrounded by an entourage of staff and security. The differences between executive protection professionals and CPP for celebrities are many times reflected by the security person's size, demeanor, and even attire. Unfortunately, celebrities believe that bigger means better and having large and muscular individuals hovering around them will ensure their safety. This is the farthest from the truth, because close protection security is based on proven tactics, principles, and practices and not presence and behavior.

A nightmare scenario for a celebrity is exiting a location and being surrounded by both fans and paparazzi in an uncontrolled environment. Security in their attempts to keep the crowd away from the celebrity will engage in aggressive behavior toward fans and paparazzi to keep them away from the celebrity. The aggressive behavior exhibited, which may consist of pushing, shoving, or shielding the celebrity from the crowd, can lead to confrontation between security and the public. Tactics or actions like this put the CPP and the celebrity in a dangerous position. The overall problem with this is it can remove security from their position with the celebrity, thus increasing the vulnerability levels for the celebrity. Aggressive behavior by the CPP when it could have been avoided can very well result in an escalated situation that may lead to an assault or injury for the CPP, celebrity, or other people. Incidents like this should not occur, and it is up to the CPP to avoid situations where a crowd can surround the celebrity, thus limiting maneuverability. Training and experience are the most critical tenets for the CPP. They must anticipate potential threats and dangerous environments before risking exposure in an attempt to keep the celebrity safe (Holder and Hawley 1998).

Celebrities come from many different industries, whether music or movies, and each will have a level of tolerance for navigating in the public domain. Celebrities will also want to participate in the party scene and will be exposed to drugs, physical altercations, dangerous weapons, intoxicated fans, and overly aggressive paparazzi. The CPP will be exposed to many dangerous and even criminal environments, in which some celebrities but not executives engage because of mutual friends or other reasons. The CPP must make a decision whether to continue to provide protection, disengage from the celebrity, or attempt to remove the celebrity from a known dangerous environment. The advent of social media increases the overall risk of the celebrity and the CPP as snapchat and other networking application alert fans and stalkers alike of the celebrity's whereabouts. The CPP must use caution when escorting a celebrity and identify potential dangers before entering a public environment. Past experiences should drive the CPP when planning security for the celebrity. Previous locations visited, which resulted in paparazzi and fan attendance, should use advance security personnel to assess and prepare the arrival for the celebrity to reduce the risk of injury to the celebrity and confrontation for the CPP (Oatman 2006). Oftentimes, celebrities will determine how they enter a location, exit a location, or interact with their fans and paparazzi. The CPP who follows orders and direction from the celebrity without analyzing the threat and risk levels is contributing to the dangers that can confront them. The principles and tactics used by protection professionals have been proven to be effective, and the CPP must adhere to them for the safety of all people with or around the celebrity.

Myths and Roles and Responsibility of the Close Protection Professional (CPP)

There are many myths associated with close protection security, and the main one is that the CPP will take a bullet for the person being protected. This is nonsense, as no federal agent, local law enforcement, or private security professional trained in close protection swears to "take a bullet" when assigned to protect a human asset. The main responsibility of the CPP is to remove the celebrity from the danger zone using a cover and evacuate (C&E) method (Oatman 2006). The CPP must always focus on prevention and the avoidance of trouble, rather than combating it. Equally, the CPP must also remain low key, calm, and

rational in many adverse and stressful situations. An effective professional providing close protection security must be able to *analyze the environment* for potential danger before they enter into it. The CPP must maintain continuous levels of training in order to remain effective as a protector of the celebrity. The ability to navigate a crisis situation in a calm and professional manner is attributed to the professionalism, training, experience, and advancements in close protection security training. Changes to the threat environment because of terrorism, social discord, or mental illness continue to change the landscape for celebrities, and it is up to the CPP to meet these security challenges each and every day. The need of the celebrity to interact with the general public is a constant and will require a dedicated and intelligent individual to ensure the safety and security of the celebrity at all times.

Protection strategies must consider threats from criminal groups, fans, and emotionally disturbed people. Many celebrities, even in the face of known threats and increase risk, continue to interact with their fan base both domestically and abroad. It is also important the CPP evaluate both the religious and cultural diversities within the USA and across the globe, as actions or just the appearance of the celebrity can result in increased levels of threat and risk. Anticipating and responding to this type of threat will be a difficult undertaking and will require comprehensive security and countersurveillance planning. The celebrity may become a victim of stalking, or an attack from a fan or mentally ill individual, so the potential danger against the celebrity must be taken seriously. Basic cookie-cutter security planning for a celebrity is not enough, and it will take analysis and comprehensive assessments of known and potential threats to ensure an effective security plan. However, overwhelming the celebrity with convoluted security procedures can equally fail because of frustration on the part of the celebrity to follow the security protocols. The CPP must provide a safe environment for the celebrity that is not overly intrusive, overwhelming, or hindering, as this can result in confusion and possible conflict between the celebrity and the CPP (Oatman 2006).

The CPP must be prepared to explain the security plan to the celebrity, and having good communication skills, manners, intelligence, and common sense will equally contribute to a successful close protection security strategy. This can help in ensuring the security plan is not only approved, but embraced by the celebrity. The CPP must remember that human emotions will come into play when formulating protective security measures; and it is up to the CPP to develop and maintain a professional relationship, not only with the celebrity, but also with the celebrity's family. There is no room for error in protection security as mistakes, redundancy, or complacency will surely result in injury, if not death, for both the celebrity and the CPP. The CPP will be tasked with many requests for services as some may be directly part of their duties and responsibilities and some may not. The CPP must communicate the specific responsibilities to the celebrity and alert anyone who requests or instructs that a service or task that is dangerous or takes the CPP away from performing their primary duties is respectfully refused.

Setting a professional standard early on will ensure the CPP and the celebrity understand what is expected and what is not tolerated. The CPP can be respectful and professional while maintaining the primary role as a protection professional. Once this rule is violated and the CPP begins conducting non-security-related tasks, the effectiveness of the CPP is reduced to being an aide. This will eventually lead to confusion and frustration for the CPP, and it will reduce the overall security environment for the celebrity. The CPP must have their hands free at all times and remain disciplined as to not violate this important rule. Allowing and accommodating the celebrity's requests for carrying packages or holding personal items will result in the CPP becoming disengaged and not focused. It is only a matter of time before a serious incident will occur resulting in injury to the celebrity and the CPP. Though many would differ with this position in a real-world environment, it must be understood that the CPP cannot, and should not, partake in activities or conduct that allows the CPP to not be tactically ready in the event of an attack (Dale 2008).

Site Advance

Conducting a comprehensive and effective site advance is a term used to ensure the location the celebrity will visit is safe; and the necessary security precautions and planning have been conducted. Site advance is a critical part of close protection security and will encompass many areas, activities, and locations the celebrity will visit. Arriving at a location prior to the celebrity will ensure that the location is safe, as well as secured to prevent an attack or incident from occurring. This important responsibility can help in preventing harm or even embarrass to the celebrity. The advance person must survey the location for dangerous conditions that could affect the safety of the celebrity and the security team. The CPP must also coordinate with the host committee representatives to confirm and verify the specific activities that will take place when the celebrity arrives.

The CPP should request support from security and engineering staff at the location to help with identifying a primary and secondary access point, internal and external threat information for the location, infrastructure concerns, and any other important information relating to the location that could affect the security and safety of the celebrity. The site advance should evaluate the exterior for large crowds, paparazzi, unusual behavior, or dangerous conditions. The arrival area should be clear and metal barriers used to "contain" the crowd and paparazzi so the celebrity is not surrounded upon exiting their motorcade. Large uncontrolled crowds can restrict the movement of the celebrity and the security team, as well as increase the risk of injury to the celebrity. If the crowd or paparazzi will not adhere and remain behind the barriers, the CPP should consider, not removing the celebrity from the motorcade, using a secondary arrival location away from the crowd or depart the area all together. The same applies for a departure, which many times will occur when the public is alerted that a celebrity is present at a location and they are now staged in front. If the crowd becomes too overwhelming, the police should be requested for crowd control and alternate departure plans considered to avoid direct interaction with the crowd. The primary reason for avoiding the crowd is the protection of the celebrity and the CPP (Dale 2008).

Countersurveillance

Countersurveillance for the celebrity can be difficult as the celebrity is usually surrounded by fans and curiosity seekers. The CPP most likely will encounter overzealous fans and possible stalkers. A potential threat must be identified and precautions taken to ensure the safety of the celebrity. A comprehensive close protection security plan must include effective and robust countersurveillance strategies. The ability of the CPP to identify potential attackers must be a priority of the CPP. When threatening or harassing information is received, the CPP must conduct a thorough investigation to ensure all information regarding the individual or group is known; so any security enhancements, if needed, are conducted. Protection intelligence requires gathering information, including any threatening communications against the celebrity toward developing a comprehensive background of the person. This should include a description of the person, any background information, such as mental illness, criminal history, and access to weapons and if they are prone to violence. A recent color photo should be obtained and shared with the celebrity, their staff, and the entire CPP team of the celebrity. The information should be continuously updated, analyzed, and used to direct the necessary security changes toward addressing the threat and reducing any risks. Threats made to the celebrity should be forwarded to law enforcement for investigation and, if necessary, possible arrest. It is important that the CPP advise the celebrity of the seriousness of following all security recommendations to ensure the highest level of safety and security (Dale 2008; USDS 1998).

First Aid

Administrating first aid must also be part of the celebrity protection plan. Providing immediate

medical treatment in the event of an attack, medical condition, or accident is the responsibility of the CPP. First aid planning and training must include CPR, providing direct pressure for trauma injuries and being aware of medical conditions of the celebrity. The CPP should be certified in first aid, and certification should be renewed every year. The CPP should be familiar with area hospitals and include in the motorcade route plans the names and addresses and if it is a Level 1 trauma center. The CPP should be familiar with any medicines or medical conditions the celebrity has to advise emergency room physicians when needed (Oatman 2006).

Threat Assessment Analysis

A threat assessment has become a valuable tool in the close protection field. Many governmental agencies and private security firms use this important tool in calculating risk. Here we learn the importance of using a threat assessment to identify potential dangers that the celebrity may encounter. When tasked with developing a threat assessment on the celebrity, the CPP must gather as much information as possible on the person (s) who may have an interest, motive, intention, and, more importantly, the capability of mounting an attack. Gauging the possibility of a potential attack is critical to the protection of the celebrity and the CPP (Fein and Vossekuil 2000). The information must include all data and other sources of information pertaining to the celebrity and his or her family. Open-source information, known threatening communications, and paid intelligence services can all help in calculating a comprehensive threat assessment. Known threateners should be investigated and a records check conducted to include criminal history, mental health, community relations, and social services. Individual motives related to the behavior of a potential attacker also play a role in the overall threat assessment process. Unfortunately, there is no one descriptive profile of an attacker. Assassins come in many shapes, sizes, intelligence, and other characteristics. However, an attacker will engage in familiar behaviors and actions before they attack.

When a person decides to mount an attack on a target, a number of preparatory steps must be taken. These steps have visual characteristics that can be observed by the CPP. These steps would most likely include acquiring a weapon, surveying security near the celebrity, and the development of an attack and escape plan. A misconception the CPP can make is to analyze threatening information based on a *presumption* that a potential attacker is always mentally ill. Research on known threateners has disclosed only a small percentage is actually emotionally disturbed. On the contrary, most attackers chose assassination because it afforded them a way of achieving a goal or to solve a problem. Additionally, another myth of a potential attacker is that a threat is made prior to the attack. Though many have written letters or made threatening telephone calls, the majority of assassins were not known or anticipated because they were anonymous until the day they decided to attack (Fein and Vossekuil 2000).

Close Protection Terminology

Close protection security uses specific terminology to ensure confidentiality and operational security for the celebrity, their family, and the security team. Exposing specific addresses, names, and activities can be very detrimental to the celebrity and the CPP, as it can alert a potential attacker where the celebrity is located, the time of arrival, the location, and what activity will take place when the celebrity arrives. The CPP should utilize "code words" that are changed regularly to ensure that any stalkers, criminals, hackers, or potential attackers cannot obtain sensitive information that could help in executing a successful attack on the celebrity. These code words can be used for residences, scheduled locations and activities, as well as motorcade movements on a secured route. The use of checkpoints, which are described over a security team communication radio, can alert the entire security team of where the celebrity is in relation to the site and within the motorcade route (Holder and Hawley 1998).

Attack on the Principal: AOP

It is likely that the celebrity may at some point be the target of an attack, whether by gun, knife, or even a whipped cream pie. Either way, if the celebrity is attacked, the CPP has failed. The CPP's ability to perceive and identify danger will be in question, and retraining will be needed. Tactics are available that many CPP use to combat a threat, but constant vigilance and attitude are equally important. One primary tactic used is known as the "arm's reach" method. The arm's reach method means the CPP is always at "arm's reach" from the celebrity so the CPP can move them from the danger zone when needed. Firstly, awareness by the CPP that a gun or other weapon has been produced in the presence of the celebrity is critical. The CPP must now act instantaneously and "sound off," "cover," and "evacuate." If the attack is from an object that is thrown, i.e., a brick, an egg, or a liquid, the "arm's reach" method is used to remove the celebrity to a safe area or location, such as a room or the motorcade. If the incident is found only to be a thrown egg and no immediate threat of injury is present, the CPP can allow the celebrity to return to the area where the incident occurred, if deemed to be safe. The use of the "clock method" to identify the location of a threat is an effective way to determine where the threat is in relation to the celebrity and the CPP. This successful tactic uses the 12 o'clock position, which consists of identifying a fixed object on a wall or location. If an attack or weapon is produced, the CPP using the clock method should identify the threat from its position in the clock. For example, if someone produces a knife at the 3 o'clock position, the CPP should *cover and evacuate* the celebrity toward the 12, 6, or 9 o'clock position if possible. The concept is to remove the celebrity from the threat and out of the immediate danger zone (USDS 1998).

Close Protection Formations

Each situation is determined by environmental circumstances that will either allow or disallow a CPP to make certain adjustments to a formation. Alternate and contingency plans should also be prepared to cover such circumstances, as weather, threats, or any other actions that may affect the security of the celebrity. Security planning is the responsibility of the CPP working with the celebrity. The protective security team should remain close to the celebrity at all times, because the overall objective is to protect the celebrity from harm and/or embarrassment. Protecting the celebrity will require utilizing effective protective formations, which can be used in certain circumstances. The formations being discussed are all part of a holistic and effective close protection security strategy to ensure that security personnel are placed strategically around the person being protected. Protective formations are all part of a structured security environment that can help circumvent any attempt from someone attempting possible harm. It must be stated that protective formations are not an absolute; however, it can help in ensuring security is placed around the celebrity to lower the risk. The following formations are used in close protection security today and have proven to be an effective and resilient tool in the overall security plan.

Lone formation utilizes *one security person* with the celebrity and can be used in both internal and external movements. The lone formation requires the CPP to stand behind the celebrity at an angle and not directly behind for better field of view and observation. Known as the number one, this person is responsible for removing the celebrity from the area when required. In order for the number one to be effective, the CPP must maintain an *arm's reach* from the celebrity at all times in the event of an attack. It is important that the CPP remain vigilant and maintain the "arm's reach" behind the celebrity at all times. Unfortunately, this is not always possible because of reluctance of the celebrity to allow the CPP to be so close. However, allowing too much distance (more than arm's reach) between the celebrity and the CPP can result in injury if the person cannot be removed from a dangerous environment quickly (Dale 2008).

Another formation utilized is known as the *slash or sweep formation*, which requires an *advance person* to lead the protective formation. This formation requires a *two-person security team*: one as the advance, who knows exactly

where the team must go, and the number one who is responsible for the safety and security of the celebrity. However, human nature will play a role in how the protective formation is effective when dealing with an attack. Instinct and human reaction many times cause individuals to engage an attacker when their responsibility may have been to the celebrity. Another formation is known as the *wedge formation*, which will require more security personnel and should be used when a higher threat level has been assessed for the celebrity. The use of an advance person, a number one behind the celebrity and another CPP positioned on the opposite side of the number one, can enhance the overall security environment. This formation is used in public settings where access by the public is possible.

Close Protection Motorcades and Route Management

A major part of the close protection security plan is the development of a robust transportation safety structure. Motorcade and route management is a primary security mechanism for the celebrity's security plan. Ensuring that the celebrity and the security team remain safe will require strategic and critical thinking skills that anticipate danger and ensure the CPP can respond quickly and effectively in the event of an attack. Motorcades can range from one or more vehicles; and though motorcade sizes may vary, the fundamentals remain the same. Vehicle transportation is considered vulnerable, because the CPP team is not in a strategic and ready position. Individuals attempting to photograph or even harm the celebrity can easily approach the motorcade. This is a dangerous scenario and is up to the CPP team to remain vigilant and anticipate any and all threats that can occur. Motorcade planning must ensure that the CPP is trained in evasive driving techniques. There are various independent and accredited schools that can train the CPP in evasive driving techniques throughout the country. The CPP driver must operate the vehicle in a safe and responsible manner at all times and only when under attack should the operator make any evasive moves.

The celebrity is the primary asset in a motorcade and whatever vehicle the celebrity is situated in the vehicle will be identified as the limo. The celebrity should be situated in the right rear of the limo, as this is done for onside arrivals. The CPP must develop secured routes when transporting the celebrity in the motorcade. The first designated route is known as the *primary route*, followed by a *secondary route*, and in certain circumstances, a *tertiary route* may be designated. Multiple routes are needed in the event of threatening information, an attack, hostile surveillance, or a traffic condition. The CPP must observe all road and environmental conditions and potential problems on a particular route. Challenges and potential threats include construction, traffic congestion, demonstrations, roadway chock points, as well as weather and pavement condition. These are just a few of the concerns the CPP must anticipate, assess, and calculate when developing motorcade routes (Dale 2008). The routes should be determined based on safety but also the ability to evacuate and retreat in the event of an attack. Safe locations or *safe havens* on the route would include police stations, fire stations, hospitals, government buildings, and even corporate locations that have security positioned in the lobby.

Motorcade Alignment and Vehicle Positioning

The positioning of the motorcade vehicles is critically important and part of a strategic design platform in close protection security. The theory of aligning cars is part of a security environment that does not expose the celebrity unnecessarily and provides tactical positioning for the CPP. After the vehicles have been inspected and secured, they are now ready for alignment and positioning. A motorcade configuration should include a lead car to pilot the motorcade. The lead car will know the motorcade routes and act as an advance toward identifying hostile surveillance or a dangerous condition that may affect the motorcade's movement. The second vehicle in the alignment is known as the limo, which was previously discussed. The third vehicle in the

motorcade is known as the follow vehicle, which will have additional security personnel who are part of the protection team. They will form a protective formation around the celebrity once he or she exits the motorcade. This is known as a secured package, and it is also utilized in many diplomatic and executive protection security details. The vehicles should be the same make, model, and color to avoid an attacker or paparazzi from easily identifying the vehicle carrying the celebrity.

The positioning of the motorcade with the limo in the center also allows the follow vehicle to become a replacement vehicle for the celebrity in the event that the limo was to become disabled. Strategies such as these have been very effective in maintaining a high standard of security for the all types of close protection security. Motorcade movement is a critical part of the security plan as the celebrity may decide to walk or jog on occasion. The motorcade must shadow the celebrity during these moves. Though this is not always possible, the security team should ensure that routes are determined if possible prior to any walking moves. Routes for the celebrity when walking should be with the flow of r so the motorcade can proceed and continue to shadow at a close distance. Counterflow is not recommended as it will cause the motorcade to reposition away from the celebrity, which increases the overall risk exposure in the event of an incident or attack (Dale 2008).

Physical Security Concepts and Residential Security

The CPP team will also be responsible for surveying and installing physical security measures around the celebrity's residence. Since many attacks, especially kidnapping attempts, occur at a person's residence, providing productive and effective security protection measures will be a necessary component of the close protection plan. Implementing physical barriers, such as fencing and motion sensor lighting, will protect the perimeter from a possible intruder. CCTV surveillance cameras should also be installed, which the CPP, as well as the celebrity, can view the property both remotely and while inside the residence. Additional security measures include a grade 1 or 2 locking mechanism, solid wood doors on the exterior of the residence, as well as anti-shattering window filming. Interior rooms of the residence should have intrusion detection sensors on windows and doors, glass break detection, and life safety equipment such as CO2 and smoke detection. Panic room consideration should also be part of the security survey, and rooms within the residence should be identified as potential panic rooms (USDS 1998).

Attire and Equipment

The CPP must wear appropriate attire that is conducive to the professional environment they are working in. Like training, professionalism, and attitude, having the proper equipment and presenting an assertive look are important in the overall protection of the celebrity. This section will describe the equipment needed for the CPP and the clothes that should be worn. When assigned to the protective security detail, the member needs to obtain certain equipment that will assist in the protection of the celebrity. Protection equipment will vary from team to team and from environment to environment. Individuals may feel the need to equip themselves with the necessary items that will do the job at hand. As a member of the security team, you are on the front lines, not only in regard to an attack, but in the public's eye. The message sent will have an impact on the celebrity and the entire team. Personal appearance is as important as training, and both need to be followed and practiced on a continuous basis. The following is a guide on the proper dress code for a member of the security team:

Males and Females

- Single-breasted, dark blue, black, or dark gray suits are preferable
- Dark-colored sport coat and slacks can also be worn
- White or light blue shirts with simple color ties
- Slip-on shoes, rubber sole, preferably black
- Golf shirt with khakis, only under nonbusiness occasions

Equipment

Communications
- Radio with surveillance kit (earpiece)
- Radio holder, pager (if needed)
- Cellular telephone. Smartphone technology is recommended

Flashlight
- Compact flashlight with extra batteries
- Writing note pad
- Working black ink pen
- Firearm (if authorized) with belt holster and extra magazine clip. Carry permit and other identification for law enforcement purposes

Definition

Corporate security is responsible for overseeing the physical protection of a company's property, personnel, data, and intellectual assets, as well as identifying, mitigating, and managing security and safety threats to the company's resilience and continuation.

Introduction

Corporate Security focuses on the application of governance practices to ensure company principles, polices, and procedures are identified and applied as designated within the organization. Two major changes in corporate security since September 11, 2001, include the types of people who serve as directors and the policies implemented (Nemeth 2018). Initially, the majority of security directors had been retired law enforcement officers who worked predominantly in inner cities, trying to reduce crime and assist the public. Corporate America's mentality was that retired law enforcement officers would be good directors because they had the experience and expertise in dealing with security and criminal matters (Nemeth 2018). Organizations today are seeking security professionals with former military experience or law enforcement backgrounds, as well as an advanced degree in business, security, or management (McCrie 2016). These directors need to know about both public and private security notions, including: community policing, crime prevention through environmental design, electronic access control and monitoring systems, loss prevention, protection of intellectual property, how to deal with active shooters, and implementing emergency management (Nemeth 2018).

Changes in corporate security's policies occurred as a result of its global function in today's society. The security management team is responsible for surveying, mitigating, and managing an organization's footprint (McCrie 2016; Nemeth 2018). It ensures the continuance of an organization when a disaster strikes through planning and strategy development. Any potential

Corporate Security, Fig. 1 12 Organization's strategies

Ethics and Compliance	External networking	Health and Safety	Internal networking
Investigations	IT Security	Physical Security	Workplace Violence Programs

threat must be considered and reviewed by security personnel (McCrie 2016). The team must also take into consideration that not all strategies will fit an organization's security profile (see Fig. 1). For example, security procedures from hospitals, retail stores, and education facilities will be significantly different. Organizations must adhere to security regulations and standards based on their city, state, and federal classifications, as well as the industries' governing bodies.

Corporate Security continues to face challenges as corporations expand and increase their profits, requiring private security to protect its assets (McCrie 2016). Many organizations are now hiring Chief Security Officers (CSO). The CSO is an organization's most senior executive accountable for the development and oversight of policies and programs (The Hallcrest Report II). The CSO is part of the C-Suite (i.e., titles beginning with "chief") which is usually the most senior executives in the organization (e.g., Chief Executive Officer, Chief Marketing Officer, Chief Financial Officer).

Chief Security Officer

The CSO is responsible for the protection of life and property of all those working at or visiting the company's facilities. The main duties of the CSO is to forge interdepartmental connections (e.g., Facilities, IT, Legal, Communications, Human Resources and Procurement) and to develop policies and strategies that safeguard and protect all assets owned by the organization. It is important for the CSO to stay current regarding all internal and external security and safety related issues. The CSO must ensure the security staff are properly trained and equipped to deal with potential issues that arise and mitigate these hazards as quickly as possible (see ▶ "Personnel Security: Training" in this encyclopedia). CSOs manage all investigations and formulate strategies to respond to serious events that may impact the organization. Events, such as labor disputes, weather conditions, power disruptions, terrorism, and active shooter incidents, can impact an organization on multiple levels. Their ability to interface with external organizations, from law enforcement agencies to local community groups, is vital to their success, as is their ability to understand accounting and budgeting responsibilities. Finally, CSOs must be able to communicate their visions to the organization effectively.

Challenges for Corporate Security Department

So, what exactly are the challenges of Corporate Security department? In this section, the six challenges that corporate security departments face (i.e., Budgets, Electronic Security Systems, Workplace Violence including Active Shootings, Fire Safety, Communications and interfacing with External Agencies) are discussed.

Security Budgets

The Chief Security Officer is first tasked with creating and maintaining a budget in efficient and effective manner (Harrison 2014). Large organizations have security in the hundreds of thousands or millions of dollars. The Corporate Security executive must interface with senior management and finance departments to ensure the security budget remains on track for the company's calendar (i.e., January 1 to December 31) or fiscal (i.e., covering 12 consecutive months, but starting in any month) year.

Two factors that security departments take into consideration are direct labor costs and operating budgets. Direct labor costs are factored by the number of employees you have within your department and the benefits you provide for them. If employees in your organization belong to a labor union, many of the costs and pay raises are covered under the collective bargaining agreement (CBA). An operating budget is a financial document that illustrates funds needed to keep the security department operating effectively. Items can range from training, to ESS, uniforms and supplies, just to name a few.

Electronic Security Systems (ESS)

The second challenge for security departments is the understanding and utilization of Electronic Security Systems (EES) your organization employs. This can include the following: CCTV's, Access Control Systems, Mail Room Detection Systems, Glass Break Detection, Electronic Eavesdropping Detection Equipment, and IT Monitoring Equipment. In many organizations, the IT department will have its own budget to protect the corporation's data and electronic files. However, when a system is breached, Corporate Security may become involved in the investigatory process working alongside the IT department (see ▶ "Investigations: Criminal" in this encyclopedia). There are a few reasons for purchasing an ESS system. The first is to protect life and property. The second is to utilize the equipment with personnel to respond to incidents faster. The third is to create systems that can track and monitor internal and external movements of personnel, visitors, and guests to ensure their safety.

Three factors must be considered when a company purchases any type of Electronic Security Systems. First, the individual responsible for the purchasing of the equipment must decide how the ESS will enhance the organizations operability. The decision will be based on whether a site survey had been conducted and regulatory requirements had been reviewed as justification to add or enhance current ESS. Specifically, the company should survey to determine what advantages the ESS component will afford a company, as well as its costs. For example, an organization seeking to add another closed-circuit television system to an existing system would need to ensure that the monitor(s) is capable of adding an additional camera(s), the length of the cable or wire run to connect the device is configured appropriately, and the correct camera is selected, such as a pan-tilt-zoom (PTZ) or stationary camera, and whether it is functional in low light conditions.

Second, the company must consider the cost associated with the purchase of an ESS. The costs can vary from product to product. It is imperative that a security professional with experience in designing and installing security systems be involved. In determining which vendor to select, it is advantageous to obtain three bidders and always write the Request for Proposals (RFP) for the bidders with two necessary components in mind. Next, conduct a Request for Information (RFI) on each company selected to submit proposals on the ESS project. The RFI is a document used to obtain information about the company which can include their products, services, or suppliers. In many large organizations, the purchasing or procurement department will assist you in undertaking this task. Finally, advise the bidders that the specific camera, monitor, door alarm, panic alarm, and housings to enclose these devices must be used. This requirement will force the bidders to submit proposals using only the requested products and materials. The price difference should be in the labor costs only, which allows an organization to conduct a comparative cost analysis.

Third, the company must develop an oversite group who will be responsible for writing policies and procedures. Determine what the primary purpose would be for installing the ESS system, that is, its specific intention. A policy needs to be written outlining the functionality of the specific ESS. For example, the best performance would be to interface the CCTV's with an alarm monitor so that when an alarm is activated, the closest CCTV(s) to that activated device should appear instantly on the alarm monitor. This allows the individual monitoring the system to observe in real time what has just happened. Procedures need to be developed instructing the operators what to do in the event of a crisis. These procedures should be reviewed after each incident or at least on a monthly basis (see ▶ "Physical Security: Exterior Application" in this encyclopedia).

Workplace Violence and Active Shooters

The third challenge is workplace violence (e.g., hostile workplace, bulling or cyber bulling, stalking, sexual harassment), with emphasis placed on active shooter training (see ▶ "Workplace Violence: Active Shooter/Terrorist Threats" in this encyclopedia). In 2016, there were 500 homicides in the workplace and 394 of those victims were intentionally shot and killed (Strom et al. 2010). Additionally, a total of 792 injuries were intentionally inflicted on workers, an increase from 646 the year before in 2015 (Caine 2018; see ▶ "Workplace Violence: Assault" in this encyclopedia). Corporate Security departments have become involved in mitigating various incidents, especially when it involves co-workers (Lindell et al. 2015). In most incidents, there is a three-pronged approach to these investigations. Usually Human Resources receives the complaint and investigates it themselves or involves Corporate Security and/or Legal (Sylves 2015). Depending what the corporate policy is, the investigation can proceed in one of many directions. At times when a victim thinks the claim was not adequately investigated, the employee will go to local law enforcement or the media. When this occurs, it is imperative to involve the organization's communications department. All inquiries should be directed to them, and other departments should be advised not to discuss the case and refer all questions to the Communications Department.

A recent report by the FBI (Silver et al. 2018) examining active shooter cases from 2000 to 2013, provided information useful in understanding the preattack factors that contributed to these incidents in which multiple people were injured and killed with firearms and bombs. All businesses will need both active shooter awareness and mitigation training (Interagency Security Committee 2015; Wallace and Webber 2018). The main information provided included that has been an increase over the past 7 years in active shooter incidents, incidents occurred predominantly in commercial settings, the majority of shooters were lone men, and that more than half of the shootings ended by the shooter either fleeing or committing suicide, particularly after law enforcement engaged with the shooter (Silver et al. 2018).

Many organizations are training their staff on how to deal with an active shooter situation. They are interfacing with local law enforcement agencies and hiring external consultants to train their staff on recommended guidelines to follow during an active shooter situation (see ▶ "Public-Private Partnerships: Training and Coordination in Disasters" in this encyclopedia). Depending on your business and your building active shooter plans will vary from location to location. The three primary objectives law enforcement communicate to the public during mitigation training are: "Run-Hide-Fight." If possible, run from the active shooter safely. If running is not an option, hide from the shooter. Once inside a secured area, lock the doors, turn off the lights, call "911" if possible and silence your cell phones. The last alternative is to grab any item in the area and use it to defend yourself and fight back against the shooter.

Corporate security must "harden" their company to prevent becoming a target. One method to do this is called Design Basis Threat (DBT) which aids in reducing or mitigating risk by implementing physical security barriers or ESS. DBT is a basis for designing systems to

protect against acts of aggression against an individual or organization. Examples include placing bollards around the perimeter of your facility to stop or deter a vehicle from crashing into your building, or ensuring all individuals entering your location have an updated access control card or visitor's badge so former disgruntled employees or visitors who attempt to re-enter the facility will be intercepted (see ▶ "Physical Security: Exterior Application" in this encyclopedia).

Fire Safety

The fourth challenge is fire safety and laws vary by jurisdiction. In many locations, their security officers act as Fire Safety Directors, Assistant Directors, Floor Wardens, Floor Searchers and Aiding the Disabled to name a few other responsibilities (see ▶ "Fire: Prevention, Protection, and Life Safety"). Corporate security departments will need to interface with facility or building managers to become familiar with the fire codes and ordinances. Within the United States, many organizations comply with the National Fire Protection Association (NFPA). The NFPA creates and maintains private, copyrighted standards and codes for usage and adoption by local governments. The NFPA works to achieve these goals by delivering information and knowledge through their more than 300 codes and standards, research, training, education, outreach, and advocacy and by partnering with others who share a similar vision and an interest in furthering their mission.

Communications

The fifth challenge is communications. Every organization thinks it is prepared for communicating during a crisis, but unfortunately, they may not be. In most instances, corporate security is one of the first departments to learn of a crisis and then it often fails to enact the communication protocol. The Communications Department/Media Information Department can be a significant partner if utilized properly. It is imperative to formulate a crisis communication team to ensure that one strong, accurate message will be sent in a timely manner notifying all stakeholders of the status before, during, and after the crisis (Lindell et al. 2006). It is also necessary to appoint one spokesperson for your organization. This individual should be part of the communications team and will be designated point person to answer all questions and inquires.

Global security departments should consult a communication specialist for every location in which their organization is located. The message will be designed consistent with the type of business it is, the stakeholders it has, and legal requirements. In the last 2 years, misinformation on social media and "fake news" have become a concern for businesses. It is important that any incident affecting the company is communicated to the public accurately particularly as individuals are able to upload and distribute information at the tap of various communication devices. Once information is out there, it is thought to be factual. It is advantageous for an organization to inform the stakeholders of the issue(s) in a proactive manner rather than stakeholders and employees seeing it first via social media.

Interfacing with External Agencies

The sixth challenge for corporate security departments is interfacing and sharing information with other city, state, federal, global, and private organizations. The CSO must become familiar with a variety of external agencies and be able to define both risks and threats to the company depending on its size, goals, structure, and business model (Nemeth 2018). To do this, the Security Professional can use the CARVER System, an acronym that represents the following attributes – criticality, accessibility, recuperabiilty, vulnerability, effective, and recognizable.

The first step is to measure public health and economic impacts of an attack (Lindell et al. 2006). For example, what would happen to your employees or organization if a medical crisis affected your organization (e.g., rubella outbreak, Severe Acute Respiratory Syndrome/SARS that occurred in 2004). The second step is the ability to access and egress from a target physically. Accessibility is the directness of the target to the threat so the CSO must consider whether the organization has created a plan to mitigate or reduce the

threat of an attack. The third step is the ability of a system to recover from an attack (Wallace and Webber 2018). The CSO should determine how quickly the organization can be operational after a crisis (see ▶ "Business Continuity Plan" in this encyclopedia). The recovery time objective (RTO) is the maximum tolerable length of time that a computer, system, network, or application can be down after a failure or disaster occurs. The fourth step involves the ease of accomplishing attack against the company. By conducting a Strength, Weakness, Opportunity, and Threat (SWOT) analysis, organizations can determine how vulnerable they are to both external and internal threats. The fifth step involves the amount of direct loss from an attack as measured by loss in production. Organizations must equate how lost revenue and reputation may affect the bottom line. In particular, the CSO must determine when a crisis occurs, what the RTO is before a company can recover from a crisis. The sixth step is the ease of identifying the target. Organizations need to focus on how the degree to which specific building, system, or network is relaxed. Once an analysis is conducted, countermeasures must be incorporated. Corporate security must conduct an author or hire an external security consulting organization to do so. Once the CARVER method is applied, it is imperative for the Security Director to reach out to other security professionals within the field, as well as to the various public sectors including city, state, and federal organizations, in order to network and share information regarding how to enhance security on a domestic and international scale.

Conclusion

Corporate security will continue to face internal and external challenges. A paradigm shift in security has occurred due to the introduction of new technology, methods, and trends in response to threats and criminal actions against corporations. As quickly as a threat is discovered in business, it is the responsibility of the corporate security department to mitigate it. This takes strategy, financing, and support from senior management to mitigate risks and operate an effective corporate security department.

Definition

According to the Department of Homeland Security (DHS 2008), an active shooter is a person "actively engaged in killing or attempting to kill people in a confined and populated area" (DHS 2017 p. 2). This individual is aggressively involved in killing or attempting to kill people in an occupied location.

Introduction

There is a plethora of information on emergency response to active shooters available through various federal, state, and local agencies. Statistics provided by these agencies help us understand various information from each shooting including age, sex, demographics, social economics, the type of weapon used, and the venue of the shooting in an effort to correlate factors trying to understand comparisons or reasons if any.

In a typical active shooter scenario, people are in the process of their daily lives, perhaps sitting at a desk, in an open area like a classroom or hospital waiting area. All of a sudden, the sound of gunfire erupts. Most people's adrenaline will increase and the flight vs fight response activates. What should people do in this scenario? Experts in law enforcement discuss two methodologies you can incorporate to save yourself. First is the "run–hide–fight" technique, and the second is the ALICE technique which means "alert, lockdown, inform, counter, evacuate." Deciding which method is best for you depends upon your location and your familiarity of the location where you are at the time.

The scope of this paper is threefold. First, the chapter will provide an overview of what can be expected after a shooting, as well as how individuals; businesses; federal, state, and city agencies; and the media react to these events. Second, the chapter will describe the types of challenges faced by the agencies, communities, and families involved and the public as well. Third, the chapter will propose ideas of what needs to be done to move forward.

Run, Hide, Fight

Individuals caught in an active shooter situation need to resort to whatever action they find the most appropriate for their circumstance. The "run–hide–fight" method is what the DHS (2008, 2017) recommends to the general public. The actions you take to survive are based on what you are seeing and hearing at the time. "Run–hide–fight" is one way of trying to remove yourself from where the shooting is taking place. If possible, escape by running. "Run" in the opposite direction of where you are hearing the sound of gunfire. Leave the building or area by running as far as possible from where you heard the shooting. Sometimes you may have to run to a location within the

building that is deemed safe. If you are unfamiliar with the building, follow the other occupants who are running as well. Don't assume someone else has phoned "911." Once you are in a safe location, notify "911" and advise them of the situation (Burke 2000).

The advice is to "hide," if you are unable to exit the facility, for whatever reason. Find a location out of the shooter's view and lock the door if possible. If locking the door is not an option, block the door with whatever furniture or materials you have at your disposal. Once it is safe to do so, notify "911" and advise them of your location. Turn off all lights, close the blinds to windows or doors if possible and place your phone on vibrate. You should never leave a secured area until law enforcement officers have arrived and properly identified themselves (Burke 2000).

If you are not able to run or hide, then your only option is to "fight," that is, if confronted by the shooter, "fight" aggressively as possible to disarm the shooter. Using anything at your disposal, including a fire extinguisher, garbage can, chair, or desk, and be prepared to end the attack by causing injury or death to the shooter. If others are available or hiding nearby and it is possible, work in teams to protect your safety.

ALICE

As referenced by the ALICE Training Institute in Medina, Ohio, they break down the methodology behind the ALICE acronym. "A" stands for Alert. Alert is when you first become aware of a threat. The sooner you understand that you're in danger, the sooner you can save yourself. A speedy response is critical. Seconds count.

Alert is overcoming denial, recognizing the signs of danger and receiving notifications about the danger from others. Alerts should be accepted, taken seriously, and should help you make survival decisions based on your circumstances.

"L" stands for lockdown. If evacuation is not a safe option, barricade entry points into your room in an effort to create a semi-secure starting point.

Our training explains scenarios where lockdown may be the preferable option and dispels myths about passive, traditional "lockdown-only" procedures that create readily identifiable targets and make a shooter's mission easier. ALICE trainers instruct on practical techniques for how to better barricade a room, what to do with mobile and electronic devices, how and when to communicate with police, and how to use your time in lockdown to prepare to use other strategies (i.e., counter or evacuate) that might come into play should the active shooter gain entry.

"I" stand for inform. The purpose of inform is to continue to communicate information in as real time as possible, if it is safe to do so. Armed intruder situations are unpredictable and evolve quickly, which means that ongoing, real-time information is key to making effective survival decisions. Information should always be clear, direct, and in plain language, not using codes. If the shooter is known to be in an isolated section of a building, occupants in other wards can safely evacuate, while those in direct danger can perform enhanced lockdown and prepare to counter.

"C" stands for counter. ALICE Training does not believe that actively confronting a violent intruder is the best method for ensuring the safety of those involved. Counter is a strategy of last resort. Counter focuses on actions that create noise, movement, distance, and distraction with the intent of reducing the shooter's ability to shoot accurately. Creating a dynamic environment decreases the shooter's chance of hitting a target and can provide the precious seconds needed in order to evacuate.

"E" stands for evacuate. Evacuating to a safe area takes people out of harm's way and hopefully prevents civilians from having to come into any contact with the shooter.

Did you know that you should break a window from the top corner as opposed to the center? Many useful techniques that civilians do not know exist and can save your life.

After an Active Shooter Incident

There will be many challenges faced by a company after an active shooter incident. The emotional and physical toll it can have on personnel

may last a long time. The effects of post-traumatic stress disorder will vary for each individual, and companies must be prepared to deal with these issues at multiple levels from employees to supervisors, individually, and in groups (APA 2019). Security and law enforcement agencies will need to reassess physical security measures. Each department in the company will need to update their business continuity plans, and human resources will need to develop strategies along with senior management to move the company forward. There are many factors to consider after an active shooter incident. There are three key factors that are essential to the continuance of a company: emotional support; human resources' challenges and goals; and business continuity.

Emotional Support

According to the American Psychological Association (2019), "We do know, though, that it is typical for people to experience a variety of emotions following such a traumatic event. These feelings can include shock, sorrow, numbness, fear, anger, disillusionment, grief and others. You may find that you have trouble sleeping, concentrating, eating or remembering even simple tasks" (para 2). It is imperative for companies to offer counseling or workshops for employees and their families and friends who have been through a traumatic event. Also, for businesses, town hall meeting is another way to advise employees what management is doing and for questions to be addressed.

According to the DHS (2017) "Recovery is a continuous process that occurs over short- and long-term incremental phases. Organizations and their staff will progress through the recovery phase at a different rate, and each will require varying degrees of assistance" (p. 1).

Human Resources Department: Challenges and Goals

Senior management needs to meet with the leaders of the human resources department to discuss and review the company's Employee Assistance Program (EAP). Human resources must focus on short-term goals and long-term goals. The short-term goals are crafted to ensure employees receive the proper medical and psychological care they require. An information hotline should be established so employees and family members can obtain medical information regarding any questions that may have about treatment.

Another short-term goal is writing and communicating current and reliable information. With social media grabbing headlines (Bowman and Willis 2003), it's imperative that reliable and accurate information be provided to employees, visitors, clients, and the media. The communications department/media information department can be a significant partner if utilized properly. It is imperative to ensure accurate and timely messaging is being delivered. If the company has a communications department, it must lead the process. If a company does not have a communications department, external consultants ought to be used. The communication plan needs to ensure that one strong, accurate message will be sent in a timely manner notifying all stakeholders regarding the status before, during, and after the crisis. It is also necessary to appoint one spokesperson for your organization. This individual should be part of the communications team and will be designated point person to answer all questions and inquiries.

The second challenge for the human resources department is establishing long-term goals. According to DHS (2017), "The long-term recovery process begins once the assembly areas are cleared by law enforcement for cleaning and the affected individuals have returned to their families and friends. The goals of long-term recovery are to help employees return to normality in their daily interactions and professional life, and to take whatever steps are necessary to return the facility and/or business to normal operations" (p. 6).

This is easier said than done. The physical or mental health status of many of the employees or their family members may never return to normal. It is imperative for human resources to continue

assisting and trying to resolve personal and work-related issues long after an incident (Wallace and Webber 2018).

Many smaller companies may not have a human resources department, security department, or emergency management department. What should they do after a crisis? They can implement strategies such as Hartford Distributors did after an active shooter event in August of 2010, in Manchester, Connecticut. An employee, Omar Sheriff Thornton, was given the option of resigning or being terminated by the company for allegedly stealing beer from the distributorship. After signing his resignation letter and being escorted from an office, Thornton removed two SR9 semiautomatic guns and began firing. He shot and killed eight coworkers and wounded two others. He then shot and killed himself. The company did not have an EAP, nor did they have trained counselors. However, Hartford Distributors reached out to surrounding companies in the community for guidance and assistance. The Manchester police department contacted area businesses in an effort to provide trauma counselors and ministers onsite, to assist with the grieving process.

Remember no two active shooter incidents are alike and no two businesses are alike. Architectural design, population, location, and employee makeup are not the same. Each business must prepare a plan for an active shooting event. Security professionals must survey their facilities and created a master plan dealing exclusively with their facility. In instance where you are a tenant of a multi-tenant building, you will need to interface with the building manager or property manager to ensure your plans interface effectively.

Stowell (2017) explained:

> Organizations affected by an active shooter event will face extraordinary challenges from the moment the first shot is fired. Even if the company is able to maintain business operations in the aftermath, the physical and emotional recovery can go on for months and years after the event. Besides reevaluating physical security measures, updating business continuity plans, and dealing with possible lawsuits, companies also have a responsibility toward their employees who have suffered severe emotional trauma. (p. 39)

Companies must weigh the options of when they can reopen their business and when it is a good time to do so. Stowell (2017) discussed the aftermath of the Hartford Distributors shooting by stating:

> An offsite location was being set up for business operations, but employees protested, saying they felt strongly about returning to the original facility as soon as possible. In the days following the shooting, 100 employees from other beer distribution plants in Connecticut, as well as in Rhode Island, came to assist the company in keeping business operations on track. A memorial service was held for the employees who lost their lives. The company president addressed workers on the front lawn, in front of a makeshift memorial, before they reopened their doors. (p. 42)

Sometimes locations where active shootings occurred are demolished to aid in the healing process. This was the case at the Sandy Hook Elementary School, in Newtown, Connecticut (Lysiak 2013). On December 14, 2012, 20-year-old Adam Lanza fatally shot 20 children between 6 and 7 years old, as well as six adult staff members. Prior to driving to the school, he shot and killed his mother in their Newtown home. Lanza committed suicide by shooting himself in the head.

After the horrific crime, the school was closed indefinitely. In January 2013 students returned to Chalk Hill Middle School in Monroe, Connecticut. Sandy Hook Elementary School was eventually demolished, and a new school was built not far from its original site. In July 2016 the new Sandy Hook Elementary school was opened.

Business Continuity

How does a business continuity plan impact business and the community after an active shooting? When a facility or a business closes due to a power outage, weather conditions, or any other reason, it is expected to reopen soon. Businesses create and implement detailed business continuity and

disaster management plans for their businesses so they can reopen quickly after an incident. Emergency managers often use the term recovery time objective (RTO). Snedaker (2007) writes "RTO is the time available to recover disrupted systems and resources. This is the time you have to get the systems back up and running" (p. 219). It is different when the business has to close for an active shooter incident. The memories, in particular if a coworker has died as a result of the shooting, never fade.

If the building is deemed a crime scene and cannot reopen for a few days, there are five areas your organization needs to address. First, consider issues experienced by your employees. Your company must ensure the employees feel safe and secure and the company's EAP is handling all issues, concerns, and questions that arise. That may require you to institute an employee 24-h hotline for assistance and perhaps increasing physical security (Wallace and Webber 2018).

Customer issues are the second concern. The business must ensure customers feel safe and secure and, despite the disruption in service, plans are in place to accommodate their needs.

The third issue involves facility-related concerns. What impact did the shooting have on the facility? Do rooms or offices have to be repainted? If laptops or important documents have been left behind, is there a process in place to retrieve them? Is your company familiar with the Corporate Emergency Access System (CEAS)? The CEAS program allows private-sector companies to apply for access cards for select employees, through a partnership with government, identifying them as "essential personnel" during a critical event, providing the ability to travel, enter affected areas, and service critical infrastructure (Wallace and Webber 2018). The CEAS program is located in the following locations: Baltimore, MD; Buffalo, NY; Philadelphia, PA; Stamford, CT; Erie County, NY; Commonwealth of Massachusetts; Nassau County, NY; New York City, all five boroughs; Rockland County, NY; State of Rhode Island; and Suffolk County, NY.

The fourth concern involves telecommunication issues. The business must consider whether there are enough available desks at other locations to accommodate employees who will be displaced. When phone systems have been impacted, the business will also need to consider what alternative plans can be made regarding the system. For example, can the network allow a specific number of employees to work remotely?

The fifth issue involves interfacing with external agencies. After an active shooter incident, it is imperative to advise employees and clients that the company has met or will be meeting with law enforcement agencies. Set up a town hall meeting with employees and family members of employees along with law enforcement agencies. Let the law enforcement agencies take the lead to discuss what happened, what they are doing, and what the company can do to try to prevent an incident like this from occurring again.

Conclusion

According to Stowell (2017), "In the case of an active shooter, U.S. companies are liable for protecting their employees as in any workplace violence incident. Under the U.S. Occupational Safety and Health Act of 1970, every U.S. employer is required to 'furnish to each of his employees' employment and a place of employment which are free from recognized hazards that are causing or are likely to cause death or serious physical harm to his employees' (p. 42). U.S. state and local provinces may also have their own relevant laws." There is protection for employees in the form of laws; however there is no guarantee that employees will feel safe in remaining in a workplace that has experienced an active shooting. The success and failure of a company will be based on their handling of an active shooter incident. How a company deals with an active shooter event before (planning and training), during (run–hide–fight), and after (recovery time objectives and robust EAPs) is

essential to the continuance of a company (Wallace and Webber 2018).

Criminals: Blue-Collar Crimes

Hua-Lun Huang
Department of Sociology, Anthropology, and Child and Family Studies, University of Louisiana, Lafayette, LA, USA

Keywords

Survival-oriented crime · Expressive offense · Instrumental Offense · Social inequality

Definition

Blue-collar criminals tend to be from low income homes and their crimes involve physical or violent interactions. Since this population is constantly facing inadequate economic resources to satisfy their needs, they perpetrate blue-collar crimes in the context of economic pressure, financial need, or impoverishment.

Introduction

In criminology and criminal justice study, scholars usually agree that crimes can be committed by people of different social classes. Blue-collar crimes are survival-oriented (i.e., the main purpose/motivation for people to commit these crimes is to solve the problems of economic hardship, livelihood crisis, or extreme poverty). Since these offenses are largely committed by low-income or lower-class individuals (i.e., persons who frequently face the challenges of financial difficulty, economic scarcity, or shortage of income), such misbehaviors are called blue-collar crimes (or crimes of accommodation).

When criminologists/sociologists are inspecting the relationship between demographic factors and blue-collar crimes, the factors and the crimes chosen for inspection always have to be specific and definite. Blue-collar crimes can be classified into three broad categories in criminology and sociology: *property crime* (e.g., arson, burglary, and shoplifting), *violent crime* (e.g., bank robbery,

home invasion, and sexual assault), and *organized crime* (e.g., gang crime, human smuggling/trafficking, and illegal drug trading).

These categories, however, must be further classified so that criminologists and sociologists can perform research on blue-collar crime. Otherwise, the explanation or finding proposed by criminologists/sociologists may be invalid or unreliable because of design/ecological fallacy or other methodological problems (such as statistical error). In the next sections, the approach used by the Federal Bureau of Investigation in classifying property and violent crimes will be summarized. Then different typologies of arson, sexual assault, and homicide will be specified. This review will serve as a basis for categorizing blue-collar crimes in this article.

Legal (or Official) Classification of Crimes: Uniform Crime Report

In terms of classifying crimes, the most important (as well as popular) nomenclature used by criminologists and law enforcement authorities undoubtedly is the Uniform Crime Report (UCR). It was developed by the Federal Bureau of Investigation in the 1920s and 30s. According to this taxonomy, crimes can be classified into two principal categories – one is *serious offense* (i.e., Index crime), the other is *petty crime*.

Index crime includes two subcategories – one is *violent (or interpersonal) crime*, the other is *property offense*. Violent crime comprises four felonies: aggravated assault, forcible rape, robbery, and homicide. Likewise, property offense is composed of four felonies: arson, burglary, larceny, and motor vehicle theft.

Unlike Index crime which, almost without exceptions, involves heavy penalties like long prison sentences, offenses classified as petty crime (e.g., domestic abuse, shoplifting, simple assault, vandalism, violation of curfew, and so forth) usually can be settled through community services, fines, and/or other mild punishments. Partly because of this phenomenon, societal reaction to petty offenses usually is weak (or slow).

In a nutshell, the UCR was formulated by the FBI in the early twentieth century. As a result, it can be viewed as a standardized categorization system of crimes (see Fig. 1).

The Elaboration of Three Index Crimes: Arson, Rape, and Homicide

After the UCR has formally become a crime classification system in the 1970s, three Index offenses (i.e., arson, rape, and homicide) were elaborated by Douglas (who was a former FBI agent) and his colleagues in the early 1990s (see Douglas et al. 1997).

According to Douglas and his coworkers, arson can be instrumental (i.e., benefit-motivated) or expressive (i.e., emotion-driven). Instrumental arson includes, but is not limited to, six varieties: employment-related arson, survival-related arson, competition-related arson, insurance-related arson, inheritance-related arson, and crime concealment-related arson (especially, burglary-, larceny-, and murder-related arson).

Compared to instrumental arson (which may allow perpetrators to obtain enormous economic benefits, such as compensations offered by insurance companies), expressive arson provides offenders with an expedient outlet to relieve

Crimes

→ I. Index Crime
- → 1. Violent Crime → Aggravated Assault, Robbery, Rape, Homicide
- → 2. Property Crime → Arson, Burglary, Larceny, Motor Vehicle Theft

→ II. Petty Crime → Domestic Abuse, Driving under Influence, Shoplifting, Simple Assault, Vandalism, Violation of Curfew, and so forth

Criminals: Blue-Collar Crimes, Fig. 1 Offenses Categorized by the Uniform Crime Report

intense, uneasy, or troubled feelings (e.g., excitement, fury, hatred, jealousy, melancholy, and so on). It can be vandalism-related arson, attention seeking-motivated arson, hero arson, revenge-caused arson, extremist ideology-motivated arson, sexual arson, and serial arson.

Like arson, Douglas and his colleagues (1997) also divide sexual assault into two main categories. The instrumental one refers to those rape cases that take place in the context of sex slavery or searching for economic profits. For example, in criminal enterprise rape, sex traffickers can continually acquire pecuniary rewards if the victims they control persistently sell sex to customers (this trade is, of course, involuntary for the victim for they will be sexually assaulted by strangers again and again).

Besides criminal enterprise rape, both primary and secondary felony rapes are instrumental as well – the former refers to the situation that when someone (particularly young male) is perpetrating an Index crime like burglary, motor vehicle theft, or robbery, he accidentally finds an opportunity to commit sex crime. Like primary felony rape, secondary felony rape is also caused by profit-seeking behaviors. Nevertheless, this type of rape is premeditated for before perpetrating burglary, motor vehicle theft, or robbery, perpetrator has already had the intention to sexually assault any females he might encounter at the crime scene.

No matter whether primary felony rape is more common than secondary felony rape, expressive rape is, without doubt, far more diversified than instrumental one in pattern. This diversification can be clearly seen from the fact that at least 12 types of expressive rape are reviewed in *Crime Classification Manual* (CCM). They are social acquaintance rape (i.e., sexual assault perpetrated by acquaintances, which is most common among all types of rape), abduction rape, anger (or revenge-motivated) rape, domestic sexual assault, extremist ideology-motivated rape, group cause rape, power assertive rape, power reassurance rape, prison rape, religion- (or cult-) related rape, sadistic rape, and subordinate rape.

After classifying arson and rape from the angle of instrumental/economic or expressive/emotional motivation, Douglas and his associates (1997) do the same in CCM for homicide. According to this categorization, homicide can be instrumental manslaughter (i.e., murdering someone for money) or expressive killing (i.e., slaying someone because of emotional reasons). Instrumental homicide can be exemplified by seven types of homicidal behavior: contract killing, gang-related homicide, murder caused by criminal competition, insurance-related murder, inheritance-related murder, indiscriminate felony murder, and situational felony murder. In the commission of felony murder, the perpetrator has the intention to kill the victim or witness when committing an Index crime like burglary, motor vehicle theft, rape, or robbery. In the commission of situational felony murder, the perpetrator does not have the intention to kill the victim or witness when committing an Index crime; nevertheless, the victim or witness is still murdered because of a condition unanticipated by perpetrator.

Unlike instrumental homicide which is purely caused by the desire to obtain economic or financial benefits, expressive murder is far more complicated in motivation (i.e., it involves many noneconomic reasons or purposes like anxiety, anger, control, domination, fantasy, gender/racial bias, and so on). With this in mind, explaining this type of homicidal behavior is always a sophisticated process for criminologists and crime investigators.

In any event, expressive homicide basically originates from highly distressed, disturbed, or distraught feelings/emotions. According to the classification of CCM, it can be argument-triggered murder, authority killing, domestic homicide, group cause homicide, hero homicide, mercy homicide, revenge-related homicide, and sexual homicide. The various types of arson, rape, and homicide discussed above suggest that blue-collar crime is an extremely intricate concept for not only can it be divided into interpersonal and property offenses, it can be classified into instrumental and expressive misconducts as well.

Categories of Blue-Collar Crime: Some Examples

Based on the discussion above, it seems adequate to argue that both crime concealment-related arson

(especially, burglary-, larceny-, and murder-related arson) and vandalism-related arson are some textbook examples of blue-collar crime. The reason for this is that according to studies and statistics (see Clinard et al. 1994; Frailing and Harper 2016; Holmes and Holmes 2009), both crime concealment-related arson (CCRA) and vandalism-related fire-setting (VRFS) are chiefly committed by people of blue-collar/low-income families in the context of economic dilemma, financial struggle, and/or hostility toward society.

Besides CCRA and VRFS, the following types of rape appear to be good examples of blue-collar crime as well:

- Criminal enterprise rape (i.e., sexual assault involved by prostitution rings)
- Primary felony rape (i.e., sexual assault committed by burglars, home intruders, or motor vehicle thieves as a result of chance)
- Secondary felony rape (i.e., sexual assault committed by burglars, home intruders, or motor vehicle thieves because of premeditation)
- Abduction rape (i.e., sexual assault perpetrated by abductors)
- Group cause rape (especially sexual assault perpetrated by gang members)
- Prison rape (i.e., sexual assault perpetrated by inmates, most of whom tend to come from working-class or lower-class families)

Finally, certain categories of homicide can also serve as model examples of blue-collar crime for in America, they were chiefly committed by low-income young males (see Holmes and Holmes 1994; Katz 1988). These homicidal behaviors include

- Gang-related homicide (i.e., manslaughter committed by hostile street gangs for the purpose of controlling turf or an illegal business)
- Indiscriminate felony murder (i.e., perpetrator has the intention to kill the victim or witness when committing an Index crime like burglary, motor vehicle theft, rape, or robbery)
- Situational felony murder (i.e., perpetrator does not have the intention to kill the victim or witness when committing an Index crime; nevertheless, the victim or witness is still murdered because of a condition unanticipated by perpetrator)
- Argument-triggered murder (i.e., homicide perpetrated by young people, particularly young males, who are at odds in a bar, tavern, public billiard room, strip club, or other places where conflicts between strangers can take place easily)
- Domestic homicide (i.e., murder perpetrated by family members, especially members of low-income Black families)

All of the categories of arson, sexual assault, and homicide listed above indicate that blue- collar crime is a tremendously complicated theme in criminology for it involves many offenses that differ in choice structuring properties – some are violent and highly risky (e.g., bank robbery), some are nonviolent and "fairly safe" (e.g., credit card fraud), some require special skills and trainings (like professional burglary), while some are nonviolent, "fairly safe," and do not entail expertise (e.g., shoplifting). Because of this complicity (see Table 1), it is obvious that researchers must clearly define their subject matter when addressing the issue of blue-collar crime.

Blue-Collar Workers/Criminals

Blue-collar crimes tend to be easier for the public to observe and experience, as well as for the authorities to investigate. Such phenomenon seems to be strongly related to the fact that most blue-collar workers do not possess an independent working space (e.g., personal office) or enjoy autonomy when performing a job. In other words, the actions of blue-collar workers during working hours normally are overseen by colleagues or supervisors and thus are observable. For this very reason, blue-collar crimes usually are perpetrated in open or public places (e.g., downtown districts of a big city, parking lots, railway stations, shopping malls, slum areas, tourist hotspots, and so forth), instead of in indoor or private settings where deviant or criminal behaviors can be easily committed in secret.

Criminals: Blue-Collar Crimes, Table 1 Some Representative categories of blue-collar crime

	Property crime	Violent crime	Organized crime
Instrumental offense [Main function: helping blue collar workers/low-income people cope with economic stress or financial dilemma]	Arson: • Burglary-related arson • Larceny-related arson • Murder-related arson	Rape: • Criminal enterprise rape • Primary felony rape • Secondary felony rape • Abduction rape Homicide: • Gang-related murder • Indiscriminate felony murder • Situational felony murder	• Nonprofessional burglary • Professional burglary • Human trafficking • Drug trading
Expressive offense [Main function: serving as an outlet for blue color workers/low-income people's resentment or other negative emotions]	• Vandalism-related arson	Rape: • Group cause rape • Prison rape Homicide: • Argument-triggered murder • Domestic homicide	• Hate crime (perpetrated by those blue collar workers/ lower-class people who firmly believe they are exploited by cold-blooded economic elites) • Criminal cult crime

The research clearly indicates that there is a positive relationship between blue-collar workers/low-income persons and blue-collar crimes.

From the viewpoint of conflict theory or Marxism, all human societies on earth (no matter whether they are ancient or contemporary) are unequal in the distribution of economic resources (even those high-income countries that have sound social security system, like Denmark, Finland, Norway, and Sweden, are not purely equal). Because of this global problem, most governments in the modern world must deal with the problem of poverty and unemployment on a regular basis.

Unfortunately, no government, at least so far, can completely solve the problems of poverty and unemployment (probably because of insufficient economic resources or inadequate economic policy). Accordingly, some individuals (especially the truly advantaged and the underclass; see Wilson 1990) fall into in deep or permanent poverty – for these persons, improving socioeconomic status is extremely difficult, if not impossible, because they do not possess those assets (e.g., college education and professional degree) that will allow people to get a prestigious or high-paying job. Unable to obtain a professional or higher-paid job, of course, suggests that low-income people (including some blue-collar workers) will keep facing the problem of poverty.

Given that certain blue-collar workers and lower-class people are the least resourceful persons in a society, these populations naturally do not have many options in handling the economic pressure caused by financial difficulty. In this regard, perpetrating crimes seems to be an effective approach in helping less resourceful individuals acquire

economic/financial resources because this tactic (even though it is illegal) does not require academic degree or investments.

In any event, blue-collar crimes tend to have the following four characteristics in common:

First, they do not originate from power, property, or prestige; instead, they spring from shortage of economic resources or economic predicament caused by unemployment (Geis and Meier 1977; Simon 2018). Second, such crimes (like burglary, drug trade, and robbery) can help some blue-collar workers and lower-income people solve short-term economic crisis (Shover and Wright 2000). Third, such crimes (e.g., burglary, shoplifting, and robbery) normally are perpetrated in places where the public can act as witnesses or interventionists. Finally, such crimes (e.g., arson, rape, and robbery) usually are not subtle or silent.

Although less typical, blue-collar or low-income individuals may also commit "white collar crimes" (i.e., crimes stemmed from power, property, or prestige). For example, blue-collar workers who serve as cashiers in a workplace that requires manual labor (e.g., auto body shop, manufacturing plant, and restaurant) will gain opportunities to access cash or other financial resources. The authority of handling cash or other assets then gives working-class or lower-class individuals opportunities to commit financial crimes, like embezzlement or larceny.

Conclusion

In this entry, the defining characteristics of blue-collar crimes, three representative categories of blue-collar crimes (i.e., arson, rape, and homicide), and some demographic features of blue-collar criminals are inspected. This inspection shows that blue-collar crimes mainly originate from social inequalities (particularly income, racial, and gender inequalities). Instrumental offenses (like burglary, shoplifting, and robbery) therefore can help some blue-collar persons/low-income people cope with (short-term) financial crisis.

In addition to instrumental offences, blue-collar crimes can be expressive offenses as well (e.g., domestic abuse, family violence, rape, and manslaughter). These "emotional crimes" usually are committed by those blue-collar workers/lower-class people who have heavy psychological burden (because of financial strain) or are annoyed by social environments. As a result, blue-collar crimes can be considered as desperate means used by certain working- or lower-class people to adapt to economic strains (or to alleviate emotional tensions).

Criminals: Cybercriminals

George Grispos
School of Interdisciplinary Informatics,
University of Nebraska Omaha,
Omaha, NE, USA

Keywords
Cybercriminal · Digital crime · Digital criminal

Definition

Cybercriminals commit or support criminal acts in a digital world. These acts can be classified as either *digital-focused* crimes, where a criminal act has emerged as result of technology, or *digital-assisted* crimes, where a criminal has used technology in a supporting capacity to commit a criminal act.

Introduction

Industry reports indicate that cybercriminals continue to target organizations around the world. The PricewaterhouseCoopers (PWC 2018) Global Economic Crime and Fraud Survey indicated that a third of all respondents had been a target for cybercriminals. The survey also reported that a quarter of the respondents were victims of digital extortion or had suffered from asset misappropriation during the last year. These increases come at a great financial cost. The 2017 Ponemon Cost of Cybercrime report estimated that the financial losses from criminal enterprise cost organizations an average of $11.7 million in 2017, an increase of 23% since the previous year and a 62% increase over the last 5 years (Ponemon Institute 2017).

The reality is that the continuous amalgamation of technology into everyday life is creating an environment that is potentially conducive to cybercrime (Grispos 2016; Grispos et al. 2019). Cisco (2011) summarized the problem with the quote "wherever users go, cybercriminals will follow" (p. 14). Hence, there is a need to discuss the impact of cybercrime on society, examine who is involved in cybercriminal activities, and investigate how cybercriminal behaviors can be effectively reduced. This entry examines the historical perspective of cybercrime, defines and characterizes cybercriminals through various demographics, and discusses what, potentially, motivates cybercriminals. The entry concludes by presenting an overview of various strategies that are being undertaken to counter cybercrime.

History of Cybercriminals

One of the first documented cases of cybercriminal activity took place in November 1988, when a university student called Robert Morris wrote a computer worm (aka the "Morris Worm"). This computer worm infected the Advanced Research Projects Agency network (ARPAnet) and resulted in 10% of the computer systems attached to ARPAnet to be shutdown. The Morris Worm also infected systems within many universities, medical research facilities, and military buildings. Morris was eventually convicted of violating United States Code Title 18, the Computer Fraud and Abuse Act and was sentenced to 3 years of probation, 400 hours of community service, and fine of $10,050 (Markoff 1990). However, one positive outcome from the Morris Worm was the establishment of the Computer Emergency Response Team Coordination Center (CERT/CC), whose purpose is to provide a central point for coordinating responses to "Internet" attacks by cybercriminals.

Since the 1980s, the number of individuals and organizations that rely on computers for their business records and other functions, both in closed (i.e., only connected within the company) and open (i.e., connected to computers within and outside the company) networks, has grown exponentially. Hence, there is a growing demand for individuals and organizations to secure personal and customer information, as well as systems that are used to process and store this information. However, the software and applications that are

executed on these systems are often vulnerable to a variety of cyberattacks, forcing software manufacturers to either release updates to prevent attacks or worse, repair the damage caused by cybercriminals. For example, malware authors around the world have caused millions of dollars in damages through computer viruses and computer network worms such as Melissa, Love Bug, and Code Red (Hoar 2005). Likewise in 2003, the SQL Slammer worm resulted in millions of individuals around the world to go without cellular or Internet service as well as the cancellation of flights from airports in the United States (Hoar 2005).

The past few years has also seen a rise in a new type of cybercrime, committed not just by individuals, but by state-sponsored groups. For example, a North Korean-backed hacking group was considered to be responsible for an attack on the film production company, Sony Pictures. This attack resulted in personal information and intellectual property being obtained and released to the general public. However, what is more concerning is that many of these state-sponsored groups now aim to cause physical damage through the digital world (Grispos et al. 2017). As a result, these cybercrimes have resulted in physical damage to buildings, the shutdown of nuclear reactors, and even medical hospitals closing their doors to patients (Loukas 2015).

Defining Characteristics of Cybercriminals

An analysis of the literature suggests that a general consensus on the term "cybercriminal" has yet to emerge, and this is perceptible in the following descriptions:

- "person (who) uses the Internet, computers and related technology in the commission of a crime" (Maras 2016, p. 4)
- "is a person who commits an illegal act using a computer with an ulterior (m)otive" (Chouhan 2014, p. 49)
- "individuals (who exploit) the speed, convenience and anonymity of the Internet to commit a diverse range of criminal activities that knows no borders, either physical or virtual" (INTERPOL 2018, p. 1)

While there is much ambiguity surrounding the definition of a cybercriminal, there have also been attempts to characterize cybercriminals from the perspective of their gender, ethnicity, and social interactions with other criminals. Several researchers have argued that most cybercriminals are *male* (Bachmann 2010; Cueto 2015; Jordan and Taylor 1998; Motoyama et al. 2011). One potential reason is that there are more male than female computer science majors enrolled in universities who subsequently become programmers, who can, potentially, turn into hackers (Cueto 2015). Evidence for this theory is visible in the number of male cybercriminals who have been arrested and prosecuted for a variety of cybercrimes. For example, Kevin Mitnick obtained unauthorized access to systems belonging to Digital Equipment Corporation, Pacific Bell, and several United States Government agencies. Mitnick was eventually prosecuted and served 5 years in prison. Similarly, Michael Calce was sentenced to 8 months "open custody" for launching several Denial-of-Service (DoS) attacks against organizations including Yahoo, eBay, and CNN.

An alternative demographic that has been examined in more detail in the last decade is related to the *race/ethnicity* of cybercriminals. The evidence suggests that most cybercriminals are Asian or of European descent, given that these are the racial backgrounds of most programmers (Cueto 2015). Moreover, this notion has been fueled by a growing number of cybercriminal incidents that are purported to have originated in countries, such as North Korea, China, and Russia. For example, Kozlowski (2014) examined three cyberattacks on Estonia in 2007, Georgia in 2008, and Kyrygysytan in 2009, with the aim of answering who was responsible and why the attacks were undertaken. Kozlowski (2014) concluded that in all three cases, these countries had tense relations with Russia, and that attacks were either carried out by patriotic cybercriminals on behalf of the Russian government or by

the Russian government itself. Russian cybercriminals continue to be attributed for a variety of cybercrimes, including a number of attacks that resulted in American companies losing tens of millions of dollars due to scams and fraudulent activities (Gregorian 2018). Similarly, as China's internet presence continues to increase, the state of cybercrime in China has been the focal point for several studies (Kshetri 2013; Lewis 2005; Yip 2011). Kshetri (2013) has reported that China often ranks in the top three countries for hosting malware, generating spam, click fraud, and being responsible for cyberattacks.

While most cybercriminals are understood to act alone, many cybercrimes are not committed in isolation (Hutchings and Chua 2016). For example, cybercriminals will compromise servers to steal credit card information, then compromise another server to store and sell this information in the near future (Hutchings and Chua 2016). This can complicate efforts to identify and associate crimes with a particular cybercriminal or group. Further confusing matter is the emergence of organized cybercriminal groups (Choo and Smith 2008). While individuals within these groups are considered highly technical cybercriminals, they are unlikely to know each other in the physical world (Choo and Smith 2008). Therefore, unless digital evidence can be found exposing a cybercriminal's organizational topology, some group members might never be known to law enforcement investigators.

Cybercriminal Motivations and Activities

Cybercriminals can be motivated by a variety of reasons to commit criminal acts, including social, political, religious, economical, revenge, and thrill-seeking motives. In the leaked classified American intelligence case, Chelsea (Bradley) Manning claimed that the information was disclosed to raise awareness of the wars in Afghanistan and Iraq, effectively *cyber-activism* (Thorsen et al. 2013). Likewise, Kevin Mitnick has often stated that committing his cybercrimes was more for fun and to challenge himself intellectually (Shimomura and Markoff 1995). However, on the other side of the spectrum are cybercriminals who commit crimes as part of a political statement or as part of an organized crime syndicate. An example of a political cybercrime is the 2014 Sony hacking by North Korea, who objected to the screening of "The Interview" and threatened to attack American cinema theaters who screened the film (Haggard and Lindsay 2015). Similarly, cybercriminals such as Nicolae Popescu who was part of a much larger group of individuals that were responsible for a wide variety of fraudulent financial activities (Lusthaus and Varese 2017).

In order to fulfill these motivations, cybercriminals will undertake a variety of different activities. Wall (2007) argued that there are three generations of cybercriminal activities: *crimes in the machine* (i.e., computer content), *crimes using machines* (i.e., computer related), and *crimes against the machine* (i.e., computer integrity). Wall (2007) speculated that in the future, cybercriminal and victim interaction will be completely automated by technology and therefore, removing the need for victim interaction. In addition to Wall's classification, several organizations and governmental bodies have attempted to develop taxonomies that define and determine a range of cybercriminal activities. However, a consensus on what should be included in these taxonomies has yet to materialize. For example, the United Kingdom's National Crime Agency's (2018, p. 1) taxonomy of cybercriminal activities include:

- Phishing – email messages asking for either security information or personal details
- Hijacking – when a cybercriminal controls your webcam, or hijacks files on a digital device and holds them ransom, usually until a financial payment is made
- Keylogging – where a cybercriminal records what is typed on a computer's keyboard or obtains screenshots of the victim's computer screen
- Ad clicking – cybercriminals directing a victim's computer, after the victim has clicked a specific link, which is often malicious
- Hacking – cybercriminals who gain unauthorized access to a computer system

- Distributed Denial of Service (DDoS) attacks – cybercriminals who attempt to disrupt the availability and "connect-ability" of a computer system

The Australian Cybercrime Online Reporting Network (2018, p. 1) provides an alternative taxonomy describing cybercriminal activities, which in some cases focus on traditional crimes where cybercriminals have extended their effect into the digital world:

- Attacks on computer systems – this includes hacking, malware, and viruses.
- Cyber-bullying – online behavior that is intended to make victims fearful and could also result in harassment.
- Prohibited offensive and illegal content – viewing, distributing, or promoting digital content that has been considered illegal or prohibited in a specific jurisdiction.
- Online child sexual abuse material – viewing, distributing, or promoting material that shows child sexual abuse. This includes grooming and sexting.
- Identity theft – cybercriminals misusing personal information or online accounts that belong to the victim.
- Online trading issues/Online scams or fraud – illegal activities related to buying or selling online.
- Email spam and phishing – cybercriminals distributing unwanted email messages or promoting material to obtain personal information from a victim.

The aforementioned techniques used by cybercriminals lead to a variety of consequences that range from minor to severe. For example, the WannaCry hack that resulted in messages from hackers demanding ransom payments resulted in 327 payments totaling $130,000 (Gibbs 2017). However, the WannaCry hack also impacted several National Health Service (NHS) hospitals in the United Kingdom, which cumulated in 19,000 medical appointments to be cancelled (Field 2018). Similarly, in 2018 Under Armour revealed that its MyFitnessPal mobile app had been hacked, which resulted in 150 million accounts being compromised. Usernames, email addresses, and hashed passwords were stolen (Lamkin 2018). Many of these user details were placed for sale on the dark web on websites such as Silk Road, an online black market (Hong 2015). Once these details are purchased by other cybercriminals, they can be used to commit additional cybercrimes (i.e., identity theft). For example, Amar Singh and his spouse Neha Punjani-Singh were found guilty of identity theft and credit card scams that resulted in victims losing $13 million (Carrega-Woodby 2012).

Countering Cybercriminals

The increasing rate of cybercrime prompts the discussion on the implementation of countermeasures to deter cybercriminals from committing such acts. These countermeasures can be broadly classified any *actions*, *technology*, or *devices* that can be applied with the purpose of preventing or mitigating the impact of a cybercrime (MacKinnon et al. 2013). It must be noted that no single solution exists to counter cybercrime, and that a number of legal and behavioral countermeasures are often needed to prevent cybercriminals from succeeding.

From a legal perspective, the increasing impact and costs associated with cybercrime has prompted European nations along with Canada, Japan, and the United States to ratify the Budapest Convention on Cybercrime (Council of Europe 2001). The purpose of this international treaty was to counter computer-related criminal activities through increased cooperation between national law enforcement agencies, harmonizing related laws, and improving the quality of cybercriminal investigations. Similarly, efforts had also been made to bring cybercriminals to justice in the International Criminal Court (Ophardt 2010).

Thus far, legal countermeasures have often been insufficient. Consequently, many organizations have implemented behavioral countermeasures in an effort to counter offenses by cybercriminals. These types of countermeasures range from raising public awareness to

educating the community on defining cybercrime, detecting and reporting cybercriminal activities, implementing policies and technical safeguards, as well as educating and training the population on safe cyber-practices (Yang and Hoffstadt 2006). Alternatively, many financial organizations such as banks, are choosing to implement biometric countermeasures (methods that rely on physical or behavioral traits, such as a fingerprint) in order to prevent cybercrimes from transpiring.

Conclusions

Cybercriminals are a distinct type of criminal, who engage in devious behavior involving some form of technology. While a consensus on the definition of the term "cybercriminals" or their activities has yet to emerge, it is very difficult for organizations and governments to ignore the problem. This is because the focus of cybercriminal activity has moved from attacks that temporarily disrupt research networks and steal classified intellectual property of the company and/or their clients' personal information to hijacking that literally shut down medical hospitals and delay patient treatments until the ransom is paid. Hence, ordinary citizens are now being impacted by cybercrime even though they are not the intended target. Therefore, it is imperative that organizations and businesses have the ability to identify, define, and investigate cybercrime, when it occurs. This means providing these organizations with tools, techniques, and laws to counter cybercriminals as they change face in the coming decades.

Definition

Criminal motives are those causes that invoke illegal actions.

Introduction

Criminal motives are those causes that invoke illegal actions. For an action to be considered illegal, an applicable law must be broken. For an illegal action to be considered criminal, the offense must cause harm to society or property. Criminal motives shed light on the "why?" behind deviant behavior and, when coupled with evidence in court, provide jurors with additional support in considering verdict.

Often confused with intent, motive constructs are external antecedents to internal thought processes (Maasberg et al. 2015). In this sense, motive and intent are two different elements with the former influencing the latter. Common law is founded on the principle that an individual is guilty of a crime when there is both a guilty action (actus reus) and guilty mind (mens rea). In Latin, *Actus non facit reum nisi mens sit rea*, or "an act is not necessarily a guilty act unless the accused has the necessary state of mind required for that offense" (Gooch and Williams 2015). Understanding a motive's impact on intent is fundamental when determining criminal punishment, as is considering the seriousness of the crime committed.

There are several ways to classify crimes; however, based on the severity of punishment, crimes can be grouped into four separate categories: felonies, misdemeanors, felony-misdemeanors, and infractions. Criminal law defines crimes within these categories to include violent crimes, such as homicide, rape, robbery, aggravated assault, burglary, larceny theft, motor vehicle theft, and arson, as well as less serious crimes, such as simple assault, fraud, vandalism, drug abuse violations, gambling, and vagrancy, to name a few.

Though federal and state law explicitly categorizes crimes, the motives that drive individuals to commit crimes are not as easily discerned. For centuries, theorists have researched and analyzed the criminal motivations that drive individuals to commit crimes. It is theorized that biological, psychological, sociological, and biosocial factors may impact decisions to commit illegal actions. However, it is also understood that more distinguishable triggers primarily impact an individual or group to act in an aberrant way. By defining criminal motives, investigators are better equipped to bring alleged criminals to justice.

Gang Membership

In law enforcement, gang dynamics is a fiercely studied and analyzed topic. Gang culture may attract potential individuals for a multitude of reasons and encourage a lifestyle that often leads to criminal activity. From acceptance to ongoing affiliation, members are motivated by both internal and external factors. Motivations often include identity or recognition (achieve a level of status), protection, fellowship/brotherhood, intimidation, and criminal activity resulting in financial gain (LAPD n.d.).

Depending on the group and region of matriculation, gangs and their leadership may require potential associates and recognized members to commit illegal acts to pledge allegiance and ongoing alignment to the group. Several different types of gangs exist, including prison, street, and outlaw motorcycle, with some groups being much more violent than others. For example, Mara Salvatrucha or MS-13 gang crimes are not primarily petty nuisance crimes; since 2012, of 500 cases reviewed by the Center of Immigration Studies, 207 MS-13 members were charged with murder. Additionally, more than 100 were accused of conspiracy/racketeering and dozens of others for drug trafficking, sex trafficking, attempted murder, sexual assaults, and extortion (Vaughan 2018).

Revenge

Synonymous with retaliation and retribution, revenge is an act of justice. Born from passion, revenge motivates individuals to hurt or harm someone for a perceived injustice. Though it is often associated with love triangles, revenge manifests itself in other relationships and environments. One prevalent and increasingly violent form of revenge renders itself in workplace violence. Some 2 M American workers are victims of workplace violence each year, and of note, in 2014, 16% of all workplace deaths were attributed to work-related attacks (National Safety Council 2018). Criminal acts of revenge in the workplace may include harassing or indecent communications, physical assault, or murder.

Though revenge is generally associated with adult behavior, it also occurs naturally within youth. Findings from a recent study conducted on 5,373 youth indicate that approximately one-half of interpersonal assaults were motivated by revenge and that a significant proportion (10–20%) of running away from home and vandalism incidents were also related to revenge (Kivivuori et al. 2016).

Greed/Money

Greed refers to the desire to always want more, yearning to fulfill some type of unsatisfied state of mind. Individuals experience greed in several aspects of life, one example being with financial gain. In this sense, greed may manifest itself in an addictive state and result in habitual gambling or with petty crime, i.e., larcenies, thefts, burglary, or robbery.

In regard to business and politics, greed often leads to corruption. For example, Enron, WorldCom, Tyco, and Freddie Mac were all big businesses that suffered great scandal after executives and leadership were the subjects of white-collar crime accusations. Recent studies have found that other factors, in addition to greed, may also motivate white-collar criminals to commit fraudulent acts. One major concept is that of convenience; that "convenience is a relative concept where white-collar crime is chosen over legitimate actions when there is a strong economical motive, ample organizational opportunities, and acceptance of deviant behavior" (Gottschalk 2018).

Drugs and Alcohol

Though drugs and alcohol are not direct motivations associated with crime, their effects on the human mind may trigger certain responses that ultimately lead to criminal behavior. In fact, approximately 80% of offenses leading to incarceration in the United States involve alcohol or drugs (NCADD n.d.). Drug offenses may include possession, distribution, specialized distribution offenses, improperly obtaining drugs from those in legal possession, drug crimes against children, and conspiracy. Alcohol offenses may include minor in possession, unlawful transportation, public drinking, driving while intoxicated, and operating under the influence.

Individuals with an addiction to drugs or alcohol are more likely to be involved with rapacious crimes. In 2016, 11.5 M people misused prescription opioids, and 116 people died every day from opioid-related drug overdoses (USDHHS n.d.). To score a fix, users may result to larceny, shoplifting, breaking and entering, and robbery. In more serious cases, addicts may solicit themselves or commit homicide for drugs.

Love

Even love renders itself in crime. Incidents may derive from domestic disputes, non-intimate partner domestic violence, familial arguments, and disagreements with friends. Some of the most horrific incidents that are perceived as acts of love are murder-suicides. More than 1,300 people died in murder-suicides in America in 2017, and during a 6-month period, 42 homicide victims were less than 18 years of age (Violence Policy Center 2018). Murder-suicide triggers may include money troubles, recent separation or divorce, custody battles, and ongoing domestic violence.

Another crime committed out of perceived love is a type of medical child abuse when a caregiver imposes a fictitious illness on a victim. This act of medical child abuse is referred to as Munchausen syndrome by proxy. By imposing a disorder on a child, the caregiver, generally the mother, feels appreciated and needed. A recent study analyzed 796 perpetrators from case reports and case series and concluded that "mothers with a personal history of childhood maltreatment, obstetric complications, and/or factitious disorder are at heightened risk for medical child abuse" (Yates and Bass 2017). By evaluating the medical history of potential perpetrators, investigators can better understand probable motives.

Conclusion

Inherently, certain crimes are linked to certain motives. Though motives may be predictive of crimes, not every crime is a result of one single motive. In fact, various motives may lead to one particular crime. For example, a gang member may commit murder on a rival gang member on behalf of the affiliated gang and because of a personal need for revenge. Or a habitual drug user may be a suspect in a domestic violence incident resulting from a disagreement. For this reason, it is essential that security professionals and law enforcement understand criminal motives, as motives tell the crime story.

Criminals: Suggestions to Improve Security Procedures

Harald Haelterman
Faculty of Law and Criminology – Department of Criminology, Criminal Law and Social Law, Ghent University, Ghent, Belgium

Keywords
Security procedures · Controls · Procedural change · Crime script analysis

Definition

Procedure: a formal or official order or way of doing things – a series of actions that need to be completed in order to achieve something.

Introduction

Security procedures are considered a critical component of an organization's overall security program (Dunham 2018). They provide guidance on how to implement, enable, and enforce existing security controls and on how to execute security-relevant business processes in a consistent and concerted manner (ibid.). At the same time, they are to be considered controls in their own right. Same as other components of a security program, they require constant fine-tuning in order to remain effective and efficient over time. This entry highlights a number of triggers or incentives for organizations to upgrade existing security procedures or to implement new ones. It further positions script analysis as a promising tool to ensure that controls and procedures remain effective and fit for purpose.

Security Procedures in the Overall Control Framework

Procedures are defined as formal or official ways of doing things or as series of actions that need to be completed in order to achieve something (Hornby 1995). In the field of security,

this can be the proper implementation or enforcement of existing security controls or the execution of security-relevant business processes (Dunham 2018). Security procedures are developed and introduced in order to ensure that these controls and processes are implemented, enabled, enforced, and executed in a consistent and concerted manner, providing a reasonable degree of assurance and predictability (ibid.). They build upon the organization's security policies and focus on guiding behavior toward a certain and desired end result (ibid.). On the other hand, they are to be considered controls in their own right. The introduction of rules or procedures intended to remove any ambiguity concerning the acceptability of conduct is considered an important strand of situational crime prevention and an effective means to remove potential excuses for nonconforming behavior on the part of those intended to obey them (Clarke 1997, p. 24).

The idea behind having appropriate security procedures in place is that whenever they are followed consistently by everyone in scope, a desired and expected outcome is to follow. This does not imply that procedures remain effective and efficient as the internal or external environment changes. Just as security policies should be reviewed and updated on a regular basis, existing security procedures require constant fine-tuning, and new procedures will need to be introduced if and when required (Dunham 2018).

Drivers for Procedural Change

Various developments or events trigger the need to have new security procedures established or existing ones reviewed. As Oliver and Wilson already noted back in 1972, "the changing scene in which security is practiced constantly brings new problems" (Oliver and Wilson 1972, p. ix). These may arise from new or changing threats, from legal and regulatory changes, from a quest for efficiency gains or the need to adapt defensive approaches to the modi operandi displayed by offenders.

It goes without saying that security controls and accompanying procedures will need to be established or revisited as *new security threats* are being recognized (Threat Assessment). These threats can emerge from new products or services being introduced (see, e.g., Clarke and Newman 2005); from political, economic, social, and technological developments taking place; or from new crime phenomena entering the scene. Rapid advances in technology and an ever-increasing dependency on information and communication systems alone, for example, have been responsible for reshaping the entire security industry and for introducing a wide variety of IT ("information technology") security measures in public and private organizations alike (Cybersecurity: Cybercrime and Prevention Strategies).

Changes to *legal and regulatory frameworks* are certainly among the most obvious triggers for organizations to introduce or upgrade security controls and procedures. These regulatory changes are often brought about by highly publicized incidents or events such as the Lockerbie bombing back in 1988, the cowardly attacks on the Madrid rail system in 2004, the liquid plot in 2006, or the recent terrorist attack on Brussels airport in 2016 (▶ Airport Security: Incidents that Changed Procedures). Other examples of incidents or events that served as catalysts for governments to impose new requirements to (listed) companies with regard to security, corporate governance, and internal control are the hijackings and subsequent attacks on the World Trade Center and the Pentagon on September 11, 2001; the early twenty-first-century economic and financial crisis; a series of corporate collapses; and a range of high-profile frauds, corruption, and accounting scandals (Alexander and Alexander 2002; Chtioui and Thiéry-Dubuisson 2011, pp. 289–290). In response to the 9/11 attacks alone, we have witnessed the introduction and further strengthening of a broad range of transborder security programs designed to protect international supply chains against acts of unlawful interference and imposing a variety of specific and binding security requirements upon operators in the industry (Haelterman 2009, p. 485; 2011, p. 390) (▶ Critical Infrastructure: Transportation Systems). In many cases the introduction of these

requirements went hand in hand with employers undertaking additional security efforts due to the perception of growing terrorist threats and to employees demanding improved security at the workplace (Alexander and Alexander 2002, pp. 148–149).

Procedural innovation may further be required when it is found that security procedures contradict procedures or requirements imposed by other functions or when interdependencies between existing controls have been overlooked. An often quoted example of *contradicting* or *competing procedural requirements* is that of a security department requiring guards to make sure that all external doors of a facility remain locked at all times versus the requirement imposed by the health and safety function to keep these doors unlocked in order not to obstruct escape routes in case of an evacuation (▶ Fire: Evacuation). Examples of *interdependencies* that may be overlooked are those between physical security measures and accompanying procedures. It is of little use, for example, to install an electronic access control system without having proper access control procedures in place (Haelterman 2009, p. 490), to install GPS ("Global Positioning System") or similar technology on vehicles transporting high-value goods without the necessary follow-up capabilities and procedures (ibid.), or to invest in a CCTV ("closed-circuit television") system without having monitoring procedures in place that are appropriate for its setup and design (Clarke 1997, p. 26) (▶ Physical Security: Video Surveillance).

Likewise, procedures may need to be reviewed when it turns out that procedural requirements overlap and result in a *duplication* of efforts or when they turn out to be *too costly* or *impractical* in one way or another. Cost and waste management constantly drive organizations to transform existing strategies and practices in an ongoing quest for efficiencies. The introduction of security measures in a business environment often requires a considerable financial investment and frequently results in additional costs and/or practical problems due to their impact on certain core processes (Haelterman 2011, p. 394). The introduction of cargo screening procedures in a transport and logistics environment, for example, delays (and adds costs to) the normal operating process (ibid.), and imposing mandatory security screening of job applicants clearly adds costs and complexity to a new employee selection and onboarding program (▶ Personnel Security: Best Practices). It is important, therefore, to always engage in an ex ante and periodic assessment and evaluation of the (financial, ethical, esthetical, and consequential) costs associated with introducing security measures and of the conditions that influence their effectiveness and efficiency (see also Haelterman 2009, 2011).

Last but not the least, procedures may require an upgrade as part of the "postmortem" activities of an actual security incident (Dunham 2018). When it shows from a detailed analysis of the *modus operandi* displayed by an offender that an existing control or procedure was either easily circumvented or turned out to be ineffective for some other reason, an upgrade is required. The next section positions script analysis as a promising tool to guide such analysis.

Tools for Upgrading Existing Controls and Procedures

While the need for establishing new procedures or for updating existing ones is sometimes triggered by events and developments that go beyond management control, this is by far not always the case. This final section positions script analysis as a useful analytical tool to help management upgrade existing security controls and procedures in reaction to a real-life or improvised security incident. Other tools worth exploring are BSA ("Behavior Sequence Analysis"), in which a quantitative method is applied to qualitative data in order to investigate the relationships between events and to anticipate and redirect potentially risky patterns of behavior (see, e.g., Taylor et al. 2017), as well as the use of virtual reality to study the crime commission process in more detail (see, e.g., van Gelder et al. 2016).

Crime Script Analysis

Derek Cornish (1994) was the first to adopt the script concept from cognitive science in support of situational crime prevention. This concept,

according to Cornish (Idem: 151), offers "a useful analytic tool for looking at behavioral routines in the service of rational, purposive, goal-oriented action" and fits in particularly well with the crime-specific orientation that is found in rational choice and allied approaches to crime control. A script-theoretic approach, yet according to Cornish (Idem: 160), "offers a way of generating, organizing and systematizing knowledge about the procedural aspects and procedural requirements of crime-commission." To (environmental) criminologists and crime analysts, script analysis provides opportunities for understanding the "step-by-step process that offenders have to go through in the commission of any crimes" (Leclerc and Wortley 2014, p. 6); and by providing a template to capture and describe each stage of that process, it further assists researchers and practitioners with identifying a broad scope of opportunities for situational interventions (ibid.).

In the fields of cognitive science and artificial intelligence, scripts have been positioned as one of the theoretical entities or knowledge structures that form the basis of human memory organization (Schank and Abelson 1977, p. 17). A script (as an "event schema") is defined as "a structure that describes appropriate sequences of events in a particular context" (Idem: 41; Leclerc and Wortley 2014, p. 6). Applied to the criminological domain, it represents the complete sequence of actions adopted prior to, during, and following the commission of a particular crime (Leclerc and Wortley 2014, p. 6). If we take the hypothetical example of a script representing a theft of cargo from a soft-sided trailer parked at an unsecured parking lot (see also Table 1), such script could provide detail on potential preparations made prior to the actual theft, on the entrance to the parking lot, on the selection of a trailer to hit upon, on the means of gaining access to the load, and on the actual commission of the theft (Haelterman 2016, p. 14). It could further provide detail on the offenders exiting the crime scene, as well as on any follow-up actions (ibid.).

Scripts can be developed from the perspective of the offender – as is the case in our hypothetical example – or from that of other actors or agents participating in the crime commission process (Haelterman 2016, p. 16). They can be turned into interpersonal scripts, providing detail on the interactions between the various parties involved (Idem: 17), and can be used to study successful, attempted, failed, or aborted crimes (see, e.g., Cornish 1994, p. 163).

Criminals: Suggestions to Improve Security Procedures, Table 1 Example of script "cargo theft from parked trailer". (Modified from Haelterman 2016, p. 14)

Script scene	Script action
Preparation	Steal a van or light truck to transport the stolen items
Preparation	Gather the necessary tools for breaking into the trailer
Entry	Enter unsecured parking lot
Precondition	Drive around in search for soft-sided trailers
Instrumental precondition	Select a soft-sided trailer to hit upon
Instrumental initiation	Approach selected trailer
Instrumental actualization	Cut hole into the tarpaulin to check the load
Instrumental actualization	Break seal/lock on the trailer back door
Doing	Off-load cargo from the trailer
Doing	Load cargo into the getaway vehicle
Exit	Exit parking lot
Aftermath	Offer stolen goods for sale on the black market

The value of script analysis to those tasked with developing and reviewing security controls is that it forces them to study the crime commission process in more detail with a potential to reveal information that may be missed during a more superficial assessment of a criminal event (Haelterman 2016, p. 19). It facilitates the identification of potential intervention points and provides guidance on where preventive measures can best be introduced (Cornish 1994, p. 164). Building upon our hypothetical example of cargo theft from a parked trailer, Table 2 provides some examples of controls that can potentially be mapped onto the script to prevent repeat victimization. Where these controls are missing, their introduction can be considered; and where they are in place but have been circumvented, it is

Criminals: Suggestions to Improve Security Procedures, Table 2 Preventing "cargo theft from parked trailer". (Modified from Haelterman 2016, p. 20)

Script action	Situational controls
Steal a van or light truck to transport the stolen items	Car alarms, ignition locks, steering locks, immobilizers
Gather the necessary tools for breaking into the trailer	Control markets for dual goods, random vehicle searches
Enter unsecured parking lot	Access controls and procedures, parking attendants, select secure parking facilities
Drive around in search for soft-sided trailers	Enhance visibility and natural surveillance, on-site patrolling, camera surveillance, raise awareness and informal social control
Select a soft-sided trailer to hit upon	Replace soft-sided trailers with hard-sided trailers
Approach selected trailer	Enhance visibility and natural surveillance, on-site patrolling, camera surveillance, raise awareness and informal social control
Cut hole into the tarpaulin to check the load	Intrusion detection, anti-slashing strips on soft-sided trailers
Break seal/lock on the trailer back door	Intrusion alarms, security seals, security locks, park trailers back-to-back or facing a wall or fence
Off-load cargo from the trailer	Enhance visibility and natural surveillance, on-site patrolling, camera surveillance, raise awareness and informal social control
Load cargo into the getaway vehicle	Enhance visibility and natural surveillance, on-site patrolling, camera surveillance, raise awareness and informal social control
Exit parking lot	Exit controls and procedures, exit searches
Sell stolen goods on the black market	Disrupt markets for stolen goods

worth assessing why they turned out to be ineffective.

Reactive, Proactive, and Hypothetical Scripting

Crime script analysis can be applied in a proactive, reactive, and hypothetical mode to identify control gaps and control deficiencies and to select the most appropriate controls and control improvements that will help to prevent (repeat) victimization (Haelterman 2016, p. 123). *Reactive scripting* refers to the application of script analysis in the aftermath of a criminal event (ibid.). *Proactive scripting*, on the other hand, refers to the development of crime scripts based on information retrieved elsewhere (e.g., shared within industry bodies, gathered from the press, from professional or academic literature, from seminars and networking activities, etc.) (Idem: 124). By means of developing and interpreting scripts in a proactive manner, those responsible for designing controls gain the ability to assess whether their own organization has the necessary safeguards in place to avoid becoming a next victim (ibid.). *Hypothetical scripting*, finally, refers to putting oneself in the mind of the offender and viewing the task of breaching existing controls from an offender perspective (Ekblom, quoted in Moreto and Clarke 2014, p. 216). The type of scripts derived from these thought experiments are referred to as *potential scripts*, describing hypothetical sequences of actions and highlighting the various tracks that an offender could follow to commit a crime (Borrion 2013, p. 4).

Conditions for Successful Scripting

As with any analytical tool, the value of script analysis will depend on the amount and quality of data that is being gathered and processed. The more detail that is available on the offender's (hierarchy of) goals, decisions, actions, and interactions with the environment and other agents, the more potential for successful interventions (Haelterman 2016, p. 129). It is a known fact, however, that crime scripts often suffer from fragmented and insufficiently detailed information

(see, e.g., Cornish 1994, p. 160; Gilmour 2014, p. 39). It is important, therefore, that crime commission is being addressed at the appropriate level of specificity during interviews and investigations in general and that sufficient attention is being paid to the quality of (internal) reporting (Cornish 1994, p. 167; Haelterman 2016, pp. 236–237).

Conclusion

Security procedures provide guidance on how to implement, enable, and enforce existing security controls and on how to execute security-relevant business processes in a consistent and concerted manner. At the same time, they are to be considered controls in their own right. Same as other components of a security program, they require constant fine-tuning. New procedures may need to be established, or existing ones reviewed, as new security threats are being recognized or as the external environment changes. Upgrades may further be required in a quest for efficiency gains or when existing controls and procedures turn out to be ineffective. This entry positions script analysis as a promising and pragmatic tool to help crime prevention practitioners break down the crime commission process with the aim to identify potential intervention points, to strengthen existing controls, or to introduce additional ones. The tool can be applied in a reactive mode to properly identify control gaps and control deficiencies following an incident or in a proactive or hypothetical mode to routinely test the effectiveness of an organization's security and control setup. As to embrace the full potential of script analysis, however, it is key to address crime commission at the appropriate level of specificity during interviews and investigations and to pay sufficient attention to the quality of (internal) reporting.

Criminals: Terrorists

James M. Duggan and James J. F. Forest
Center for Terrorism and Security Studies,
University of Massachusetts Lowell,
Lowell, MA, USA

Keywords
Terrorist · Extremist perpetrator · Radicalized criminal

Definition

Terrorists are criminals who commit or directly support acts of violence in order to achieve some type of sociopolitical objectives.

Introduction

This chapter examines the groups and individuals who commit or directly support acts of terrorism. The phenomenon of terrorism itself will be covered in other chapters of this volume, including ▶ "Terrorism: Domestic" and ▶ "Terrorism: International". Terrorists are widely considered a distinct type of criminals. They consciously choose to kill, maim and destroy, and also routinely engage in money laundering, theft, fraud, extortion, smuggling (including drugs, weapons, and humans), kidnapping, bank robbery, and many other kinds of criminal activity. But terrorists generally loathe being labeled as ordinary criminals, preferring to use labels like "freedom fighters" or in the case of some religious groups, "holy warriors." And as described later in this chapter, terrorism is also viewed as a type of political violence.

Generally speaking, terrorists are not crazed killers but instead are usually rational actors who employ terrorist tactics in a calculated effort to magnify their relatively meager resources, draw attention to their plight, and garner support for their cause (Hoffman 2017). Further, the strategic goal of most terrorists is not to kill a lot of people but rather to kill a relatively few and strike fear in the hearts of many, in order to coerce the behavior of a society and its government in ways the terrorists feel will help them achieve their political or social objectives (Forest 2018).

This underscores the communicative aspect of their crimes; unlike many other violent criminals (who tend to avoid the media), terrorists often claim responsibility for attacks and try to justify their violence through their ideology, an articulation of their grievances and goals. There are many different ideological categories of terrorism, including ethnonationalist, left-wing, right-wing, and religious. Within each of these categories, there is a wide spectrum of groups and goals. For example, the category of religious terrorism includes Salafi-Jihadist groups like Al-Qaeda and Islamic State, Shiite militia groups like Hezbollah, Christian antiabortion extremists like the Army of God, and even the Japanese Buddhist cult Aum Shinrikyo. There are also terrorists who use violence on behalf of extreme goals related to environmental protection or animal rights. Each of these ideological categories will be described in this chapter, along with some examples of relevant individuals and groups.

Beyond the ideological dimension, there are also many other differences among terrorists. To begin with, researchers have sought in vain for common attributes among terrorists, but the evidence shows that they can be any age, ethnicity, or religion and from any socioeconomic or

educational background (Hoffman 2017; Forest 2018). Both men and women have been terrorists, even suicide bombers (Hoffman 2017; Forest 2018). Some terrorists may have signs of mental illness, but researchers have found nothing that would separate them from other mentally ill individuals who engage in non-terrorist criminal activity (Horgan 2005; McCauley 2007; Corner and Gill 2015). There are also many different roles an individual could play within a terrorist group, from explosive expert to budget manager, logistician, driver, propagandist, and many more (Horgan 2009; Forest 2018). This complicates matters for law enforcement and court systems when trying to prosecute individuals accused of terrorist activity. For example, should a terrorist group's bomb-maker be treated the same as another member whose role was financial management or document forgery? These and other issues will be addressed in the chapter ▶ "Investigations: Terrorism".

Overall, as this chapter will illustrate, identifying and explaining who is (or is not) a terrorist is not as easy or straightforward as some politicians or media pundits would have us believe. The chapter begins with a brief discussion about the definitional challenges of terrorism and then will review the ideological categories that have motivated most terrorists around the world. Attempts to identify a common demographic profile of terrorists will be reviewed, and examples of particularly prominent terrorists will be used to illustrate the diversity within this category of criminals. Finally, the chapter will conclude with some thoughts about the future of research on terrorists and implications for security and emergency management.

Conceptualizing Terrorism

Terrorism is an extremely complex phenomenon that is open to interpretation and subject to competing opinions among researchers. Consistent with this complexity, there are many definitions of terrorism, not only among individual researchers but also among the various government agencies that contribute to counterterrorism efforts within the USA. For instance, the US Department of State employs the definition provided by Section 2656f(d) of Title 22 of the United States Code, which defines terrorism as "premeditated, politically motivated violence perpetrated against noncombatant targets by subnational groups or clandestine agents," and the Department of Justice defines terrorism as "the unlawful use of force or violence against persons or property to intimidate or coerce a Government, the civilian population, or any segment thereof, in furtherance of political or social objectives" (Hoffman 2017). Yet another definition is offered by the Global Terrorism Database (GTD), a tool frequently used by terrorism researchers and policymakers, which defines terrorism as "the threatened or actual use of illegal force and violence by non-state actors to attain a political, economic, religious, or social goal through fear, coercion, or intimidation" (Crenshaw and Lafree 2017, p. 23). In general, the diversity of definitions used by scholars and government agencies can be problematic when conducting terrorism research or investigations.

Despite the lack of clarity presented by the various definitions, there are some characteristics of terrorism that are generally accepted by researchers. One of these characteristics is that the violence targets noncombatants, which includes off-duty military and law enforcement, as well as civilians, all of which violates international humanitarian law (Hoffman 2017). In addition, the targeted noncombatant victims of the attack are not the true intended victims of the attack but rather are victimized in order to inflict psychological trauma and "terrorize" the greater society (Horgan 2009). The fear and "terror" inflicted on society are driven in part by the apparent randomness of the attacks and the ferocity of the methods employed, such as beheading hostages and killing women and children (Crenshaw and Lafree 2017).

In addition to being a form of criminal activity that causes psychological trauma, terrorism is also viewed as a type of *political violence* (along with insurgency, guerilla warfare, rebellion, etc.). Terrorists use acts of violence as a way to achieve some type of political goals. Some may want

to overthrow an established government (the classic definition of insurgency), like the Taliban, Al-Qaeda in the Arabian Peninsula, and the Islamic State (Crenshaw and Lafree 2017). Others want the power to control a specific territory (like Hamas or other Palestinian groups) or perhaps even establish an ethnically homogenous "homeland" (like the Basque group ETA in northern Spain). Even religious terrorists are seeking to achieve some kind of political objectives, from establishing an Islamist Caliphate in the Middle East to stopping the practice of abortions in the USA (Forest 2018). Thus, understanding the motives, goals, and objectives of terrorists is necessary for researchers, policymakers, and practitioners.

Motivations of Terrorists

Perhaps the most distinguishing feature of terrorists, compared to other violent criminals, is the nature of their motivations. While other terrorists may carry out acts of violence for profit, revenge, control of drug trafficking routes, and so forth, terrorists articulate their motivations in a broad range of ideological statements. In fact, terrorist groups over the past 120 years have shown a keen interest in shaping perceptions about their activities and efforts to justify their criminal activities as necessary for achieving some preferable future (Forest 2018). There are many categories of ideologies, including ethnonationalist/separatist, left-wing, right-wing, and religious, each of which will be briefly explained below.

The most distinguishing aspect of ethnonationalist/separatist groups is their focus on physical and political geography. The ideology of terrorists in this category is driven by their desire to wrest control of a geographic area from the government in order to establish an independent state for those of a particular ethnicity, like the Chechens in Russia, Kurds in Turkey, Basques in Spain, or Tamils in Sri Lanka. And unlike the ideologies of other terrorist groups, the membership of ethnonationalist/separatist groups is limited by their ethnicity (Forest 2018).

Left-wing terrorists are driven by a utopian vision of a society that provides greater equality through the implementation of a communist government (Forest 2018). Often referred to as Communist, Maoist, or Marxist-Leninist, the ideology of left-wing terrorists is often consistent with Russian revolutionaries who galvanized the working masses to revolt against the government. Left-wing terrorists incite class warfare but are willing to allow anyone to join their cause. While not as common today, left-wing terrorist movements were prominent during the 1960s through 1980s, including the Red Army Faction (RAF) in West Germany, the Red Brigades in Italy, the Weather Underground in the USA, and Sendero Luminoso in Peru.

Right-wing terrorists are often described as either revolutionary or reactionary; the former usually target the government, while the latter may focus on countering the efforts of left-wing movements or threat to the status quo (Forest 2018). For example, the Ku Klux Klan (KKK) became a well-known right-wing terrorist movement in the USA that blocked social reconstruction policies and civil rights in the south. Many right-wing terrorists are anti-leftist, anti-liberal, religiously extreme, anti-government (e.g., the sovereign citizen movement in the USA), anti-gun control, or paramilitary/militia in nature, and some are also racial supremacists (including the Aryan Nations, The Order, Hammerskin Nation, and the American Front), targeting the members of minority groups whom they perceive as a threat.

And finally, the largest and most prominent category of terrorist ideologies today is religious. The past half-century has seen the rise of myriad Christian, Jewish, Sikh, Buddhist, Hindu, and Islamist terrorist groups, all of whom are inspired by the belief that terrorism is necessary to achieve (their interpretation of) God's will and that the truly pious terrorist is at war with those whose destiny is eternal damnation. From Al-Qaeda and the Islamic State to Hamas (in Israel), Hezbollah (in Lebanon), or the Army of God (a violent anti-abortion movement in the USA), religious terrorists have much in common. More than other categories of terrorists, the religious extremists

are absolutist (you are either with them or the enemy, there are no innocent bystanders) and supremacist (their interpretation of the faith is the one and only truth). This combination often means a negotiated compromise to address their grievances is impossible.

This category also includes some of the only examples of terrorists who have engaged in attacks using weapons of mass destruction. For example, Aum Shinrikyo was a Japanese religious cult that integrated elements of esoteric Buddhism, Hinduism, messianic Christianity, and apocalyptic prophesies. In 1995 Aum Shinrikyo launched a sarin nerve agent attack on a Tokyo subway that left a dozen dead and more than 3000 injured. Another religious cult, the Rajneeshes, used salmonella to poison a local population in the state of Oregon. And most recently, the Sunni jihadist group Islamic State used chemical weapons (including chlorine, phosphine, and mustard agents) dozens of times in Iraq and Syria over a 4-year period. Of all the terrorist groups currently threatening civil societies worldwide, religious terrorists account for an overwhelming majority.

These various ideologies shape a terrorist group's recruitment efforts, tactics, and targets. For example, left-wing terrorists typically target government buildings and centers of capitalism, as well as symbols of authority and power, such as police stations, politicians, industry, and military facilities. Meanwhile, animal rights extremists will target animal research laboratories and the businesses that finance them, and right-wing groups will target members of a minority population or perhaps a synagogue. Similarly, an attack against a particular target will likely indicate the type of ideology motivating the group or individual responsible for that attack.

Throughout these ideological categories, some common themes can be identified. First, the grievances articulated by the terrorists often include some complaint about government legitimacy (or lack thereof). According to Ted Robert Gurr's theory of relative deprivation, (Gurr 2016 [1970]), the risk of political violence in a country rises as the perceived legitimacy of a government declines. Contributing factors to perceived illegitimacy of a government include corruption, repression, indiscriminate violence, and incompetence. Sometimes, a terrorist group will carry out violent attacks in order to provoke a violent overreaction by the government in order to negatively impact the legitimacy of the regime and generate more support for the terrorist group.

Other grievances that could motivate an individual toward terrorism include structural disadvantages that exclude particular segments of a society from economic, educational, or political opportunities or the provision of social services. These contribute to a gap between an individual's aspirations for a better life and opportunities to achieve those aspirations, generating significant frustrations. However, the research also indicates that the most poverty-stricken regions of the world are no more likely to spawn terrorists than a wealthy country. In fact, there are many impoverished areas of the world that have produced no terrorists, while a significant number of today's jihadists and right-wing terrorists were raised in affluent neighborhoods, went to college, and even became engineers and physicians (Forest 2018). The broad range of personal grievances and frustrations, in turn, help explain why the majority of terrorist attacks worldwide are domestically oriented – that is, they are perpetrated by citizens or residents of the country in which the attack occurs. Despite what today's overhyped media coverage and political rhetoric about international terrorism suggest, domestic contexts have always had a far more powerful impact on motivating a person toward terrorist activity.

Another common dimension among many religious, ethnonationalist, and right-wing terrorists is "othering," loosely defined as identifying a specific population or subgroup (e.g., Jews, Protestant loyalists, blacks, "infidels," etc.) as the primary source of evil. Adherents of right-wing terrorism are driven by a particularly strong sense of "othering" that dehumanizes those they perceive of as their enemy, while the "othering" component of religious terrorism is even more radical and contributes to their zero-sum worldview.

Overall, because terrorism is a highly contextual phenomena, we must consider the

socioeconomic, political, and cultural environment that contributed to the motives of an individual to engage in terrorist activity. When examining incidents of terrorism, we must remain cognizant of the fact that terrorism does not occur in a vacuum; there is a constant interplay of myriad socioeconomic and political factors, as well as interpersonal relationships and group dynamics that provide for the environment in which individuals make rational choices. Further, it is important to remember that individuals from virtually all walks of life have been drawn into terrorist activity.

Demographics

While motivations may be the most central element separating terrorists from other kinds of violent criminals, some politicians and media pundits have attempted to portray a certain type of individual as most prone to being a terrorist. In today's politically charged environment, personal characteristics such as young, Arab, male, and immigrant have been misappropriated by some as proxy representations of the terrorist threat within the USA. And yet, nearly five decades of research by thousands of scientists and scholars have found no evidence of any common personal traits or characteristics that would help us predict the likely risk of involvement and engagement in terrorist activity (Horgan 2005). Instead of a common terrorist profile, the evidence reinforces the point made earlier in this chapter: individuals consciously choose whether to perpetrate or support acts of terrorism. Further, individuals from virtually *any* background can choose to engage in terrorist activity.

Some researchers have questioned whether mental illness might play a role, arguing that surely only crazy people would be able to justify to themselves the horrific crimes inflicted by terrorists upon innocent civilians (McCauley 2007). And yet, empirical research indicates that terrorists are rarely mad, very few suffer from personality disorders, and there is little evidence that terrorists are suffering from psychopathology (Hoffman 2017; McCauley 2007; Silke 2004). In fact, research has shown that terrorist organizations most often shun those who display any signs of mental illness, unless there is a specific tactical use for them – for instance, the Provisional IRA, or PIRA, employed the mentally ill to beat up members who got out of line but would not deploy them in an ordinary operational capacity (Horgan 2009).

One exception to this body of research may be found among terrorists who carry out attacks without the direct involvement of an established organization – the so-called "lone wolf" phenomenon. For example, a recent study (Corner and Gill 2015) suggests that terrorists who are not members of an organization are more likely to suffer from mental illness than members of the broader population. Further, they found that lone actor terrorists were significantly more likely to suffer mental illness than terrorists who were members of an established group. More research in this area is needed, but the study reflects an important modern challenge for security and emergency management professionals: how to respond to the lone actor terrorist.

Forest (2018) prefers the term "do-it-yourself" terrorists rather than "lone actor" or "lone wolf," as true lone actors are extremely rare. In this description, the do-it-yourself terrorist is one who has not had any direct operational support or training from an established terrorist group but was simply inspired to plan and execute a terrorist attack entirely on their own. While a terrorist group's ideology may provide them with a perceived justification for the act of violence, the individual chooses the target, weapons, and timing for the attack. During the late 1880s through the early 1900s, a wave of anarchists in Europe and the USA were the most prominent form of do-it-yourself terrorism, but more recent examples in the USA include the 1995 bombing of the Murrah Federal Building in Oklahoma City by Timothy McVeigh and the 1996 bombing of the Atlanta Olympics by Eric Rudolph, both of whom are considered right-wing terrorists in the research literature. And the last two decades have seen the rise of the do-it-yourself jihadists, inspired by the leaders of Al-Qaeda or the Islamic State to carry out terrorist attacks in Europe and

the USA. Some well-known examples include Nidal Hasan's attack at Fort Hood in 2009, the attempted attack against the New York subway by Najibullah Zazi and two of his friends that same year, the Tsarnaev brothers' attack against the Boston Marathon in 2013, and the mass shooting at an Orlando nightclub by Omar Mateen in 2016. The diversity of backgrounds and motivations among do-it-yourself terrorists reinforces the central fact that a common "terrorist profile" is inherently elusive. As a result, the question of who becomes a terrorist and why can only be answered by analysis that includes a broad range of contextual factors and influencers.

Terrorist Methods

Many kinds of crimes have been considered acts of terrorism when perpetrated by individuals pursuing some kind of sociopolitical agenda, as described above. One of the most common forms of terrorism has involved bombings against a wide range of targets, from public transportation to hotels, government buildings, and marketplaces. The bombs used in these attacks vary widely in size and sophistication, from the donkey cart, gunpowder, and shrapnel used by the anarchist Mario Buda in the 1920 Wall Street bombing to the two backpack pressure cooker bombs used by the Tsarnaev brothers in the 2013 Boston Marathon attack. Recently the highly unstable chemical explosive triacetone triperoxide (TATP) has been used in several jihadist terrorist attacks including the July 2005 bombing of the London Underground, the 2015 Paris attacks, the 2016 Brussels attack, and the 2017 Manchester attack. Since the introduction of suicide bombers by the Lebanese terrorist group Hezbollah in the early 1980s, there has been a global proliferation of this distinct method of delivering the explosives to the target (Hoffman 2017; Forest 2018). While the ethnonationalist group Tamil Tigers in Sri Lanka were the world's leading suicide bombers during the 1990s, we have since seen a global proliferation of this tactic involving mostly jihadist groups from Nigeria and Somalia to Pakistan and Afghanistan. Some of these groups have even deployed women and young children as suicide bombers (Forest 2018).

Beyond explosives, terrorist attacks have included a variety of other weapons, as demonstrated by the 2017 knife attack at London Bridge, ramming vehicles into crowds (e.g., Nice, 2016, and New York City, 2017) or intentionally crashing commercial airplanes into buildings (September 11, 2001). Terrorists have also engaged in kidnapping and hostage-taking for over a half-century, sometimes to bargain for policy concessions or an exchange of prisoners (e.g., the Red Army Faction during the 1970s) but increasingly to demand sizable monetary ransoms (e.g., the Abu Sayyaf Group and Al-Qaeda in the Islamic Maghreb, among several others). In Iraq and Syria, terrorists have posted videos online showing them beheading a number of western hostages as a warning to their enemies. This reflects one of the most important factors that distinguish acts of terrorism from other criminal acts – taking credit for the violence is part of the communicative strategy of terrorism. Today, terrorists used video cameras and social media to amplify the impact of their attacks as a way of generating more fear among the general public, in the belief that this will help them achieve the sociopolitical goals of their terrorist movement.

Conclusion

Obviously, nobody is born to be a criminal or terrorist. Terrorism is a type of deviant criminal behavior that is learned and can be motivated by a broad range of goals, contexts, and individuals. Much of the research on terrorist motivations has focused on an individual's perceptions, like "perceived legitimacy of the regime," "perceived threat," or "perceived opportunities." This underscores the simple fact that virtually anyone – under the right conditions – can become convinced to perpetrate or support acts of terrorism. Further, in addition to the impact of their surrounding contextual factors (political, socioeconomic, etc.), an individual's decision to engage in terrorism is influenced by friends, colleagues, terrorist group leaders, radical clerics, or even family members.

Terrorists are a distinct subcategory of criminals, defined by the sociopolitical nature of their motivations, and they engage in much more than just violent forms of criminality, to include drug smuggling, money laundering, theft, kidnapping, and much more. Security policies and strategies to combat terrorism require a broad range of intelligence and law enforcement actions as well as relevant socioeconomic policies that address the underlying contextual factors motivating the terrorists.

Criminals: White-Collar Crimes

Zakir Gul
Criminal Justice Department, State University of New York (SUNY), Plattsburgh, NY, USA

Keywords

Crime · Criminal · White-collar crime · White-collar criminal

Definition

The Federal Bureau of Investigation (FBI 2019; see chapter ▶ "Investigations: Criminal" in this encyclopedia) defines white-collar criminals as business and government professionals who commit crimes that are "characterized by deceit, concealment, or violation of trust and are not dependent on the application or threat of physical force or violence" and have a financial motivation rooted in the desire "to obtain or avoid losing money, property, or services or to secure a personal or business advantage."

Introduction

The terms *white-collar criminal* and *white-collar crime* have been discussed conceptually and theoretically since Edwin H. Sutherland coined the terms 80 years ago. The widely accepted literature in criminology held that crimes were committed by people from low socioeconomic communities or by people with psychological or biological problems, making any other possibility a radical concept at least then. Over the years, the definition of what constitutes white-collar crime has evolved and took new forms.

White-collar criminals tend to be wealthy middle- or upper-class men who are well-educated, employed, respected and trusted, nonviolent, with no prior criminal or disciplinary record, and commit crime in a legal corporate or professional setting mainly for financial and material gain. White-

collar crime, whether in the past or today, can have serious consequences for and impact on society, individuals, institutions, and the environment. With a single act, a white-collar criminal, whether an individual or corporation, can harm and victimize (directly or indirectly) many people financially, physically, psychologically, and sociologically. This crime can financially impact the society more than all blue collar crimes (see chapter ▶ "Criminals: Blue-Collar Crimes" in this encyclopedia) combined. For example, a white-collar criminal engaged in a Ponzi scheme caused investors in the scheme to lose $65 billion on paper (Fishman 2011) and a total of $90 billion in cash and on paper (Memmott 2011). After the leader of the scheme confessed to the crime, his son (Fishman 2011) and some of the investors (Cohen et al. 2017) committed suicide. In some other Ponzi-scheme cases, the perpetrators killed family members before taking their own lives (Saxby and Anil 2012).

Companies may inflict financial harm with their actions such as bankrupting and stealing pensions on the society. Further, they can also give physical harm that may affect the health and lives of the people. Pharmaceutical and food industries are just two examples that are being exploited by the corporations. Many victims of white-collar crime, however, may not even be aware that they are being victimized because the perpetrator is perceived as being honest (Cullen et al. 2009), trustworthy (Friedrichs 2010; Shapiro 1990), respected, and privileged (Shover and Wright 2001). White-collar criminals succeed and are able to conceal their illegal action by winning the trust and respect of their victims.

This chapter begins with describing the demographics and characteristics of white-collar criminals. It continues with the sections of theories and types and forms of white-collar crime. Finally, the impact and consequences of a white-collar criminality are discussed before the conclusion section.

Demographics

White-collar criminals typically are males in their 40s and 50s who have a middle- or upper-class socioeconomic status (ACFE 2018; Gottschalk 2014; Friedrichs 2010; Wheeler et al. 1988). White-collar criminals usually are *male* (Sutherland 1940; Wheeler et al. 1988; Blickle et al. 2006; Daly 1989). In one study, the majority (69%) of the occupational fraudsters were found to be males (Association of Certified Fraud Examiners [ACFE] 2018). One explanation for females as not being many white-collar criminals is the less opportunity of females due to some gender segregation and inequalities in the workplace (Benson and Gottschalk 2015). Daly (1989, pp. 789–790) found that "men's white-collar crimes were both petty and major, but almost all the women's [crimes] were petty." Daley noted that "although half or more of the employed men were managerial or professional workers, most employed women were clerical workers." Daley also found that female white-collar criminals were younger and had a lower level of education compared to male white-collar criminals.

Unlike blue-collar criminals, white-collar criminals tend to be *well educated* (Ragatz et al. 2012; Wheeler et al. 1988). A recent study found that 76% of the occupational fraudsters had some postgraduate education or had earned a degree from a university (ACFE 2018). White-collar criminals also are employed, homeowners, and generally *wealthier* than common criminals (Gottschalk 2014; Wheeler et al. 1988).

White-collar criminals usually are *middle-aged* and *older* than conventional criminals (Gottschalk 2014; Friedrichs 2010; Wheeler et al. 1988). ACFE (2018) reports that the majority (61%) of the occupational fraudsters are between the ages of 36 and 55 (19% at ages 36 to 40; 19% at ages 41 to 45; 14% at ages 46 to 50; 9% at ages 51 to 55), whereas only 5% of the offenders are under the age of 26. Further, 10% of the perpetrators are between the ages of 26 and 30; 15% of them are between the ages of 31 and 35. However, even though the age group of 56 and older makes up only 9% of the study sample, it is responsible for the largest median losses (56 and older ages for $ 835,000 compared with 30 or younger ages for $ 63,000).

Characteristics

White-collar criminals have specific qualities that aid them in committing crime. First, they are highly *trusted* individuals. Exploitation of this trust is at the core of their misdeeds, and it is what enables white-collar criminals "to rob without violence and burgle without trespass" (Shapiro 1990, p. 346). Some scholars, therefore, refer to white-collar criminals as *trusted criminals* (Friedrichs 2010) and their crimes as *crimes of trust* (Menard et al. 2011).

White-collar criminals are *respected*. They are "respectable or at least respected business and professional men" (Sutherland 1940, p. 1) who exploit this respectability. This respectability also can arise from factors such as moral integrity, a legitimate position or occupation, or an outward appearance of acceptable or superior status (Friedrichs 2010). Respectability can prompt people to trust white-collar criminals, thereby making it easier to engage in illegal activity.

White-collar criminals usually are *first-time offenders*, meaning that they do not have a prior record of criminal background, or employment-related disciplinary actions. ACFE (2018) reports that the vast majority (96%) of the perpetrators were not previously convicted of a fraud-related offense. In the same vein, the majority (85%) of the perpetrators were never punished administratively or terminated for fraud-related conduct before, either.

White-collar criminals can be *charismatic*. White-collar criminals, particularly those in leadership positions, have been known to use their charisma to commit white-collar crime (Bucy et al. 2008). For example, if the followers of a charismatic leader believe in their leader, the followers might choose loyalty over honesty, or the followers may feel powerless to question or confront the leader and therefore simply do what they are told to do.

White-collar criminals usually are *nonviolent* (Friedrichs 2010). Although many white-collar crimes have led to serious physical harm or death to some of the people involved, the perpetrators' use of violence against those victims is not believed to have been directly inflicted or intentional (Friedrichs 2010). White-collar crime, therefore, is viewed as a nonviolent crime. In such cases, the intent of the crime was not to injure or kill but to reap economic benefits or occupational success in a legitimate occupational context. Some researchers believe that the unintended injuries and deaths are inevitable side effects (Benson and Simpson 2009) or outcomes resulting from acts of inadvertence, omission, and indifference (Geis 1972).

White-collar criminals may, however, apply to violence to deceive people and cover their white-collar criminal activity. This approach led to the coinage of the concept known as "red-collar criminals" (Perri 2016). Red-collar criminals engage in violence to silence people "who are in a position to detect and/or disclose their fraud schemes: hence the name fraud detection homicide describing the motive to classify the murder" (p. 62).

Theories and Motives

Some of the theoretical approaches that give explanations for the motives of white-collar criminals are presented in this section. Given the complex and multifaceted nature of white-collar crime, no "single theory or explanation can comprehensively explain all forms or nuances" (Friedrichs 2010, p. 247), but each theory covers some part of the phenomenon.

One common motive for white-collar criminal is *greed* (Bucy et al. 2008; see chapter ▶ "Criminals: Motives" in this encyclopedia). This greed often is driven by the desire to acquire monetary and/or financial benefits and gains. Bucy and her colleagues (Bucy et al. 2008) found that greed has been the primary motive for white-collar criminals, especially for persons in leadership positions. Fear of failure and fear of losing one's job or lifestyle also motivate people to engage in white-collar crimes (Bucy et al. 2008, p. 407).

Sutherland explained the acts of white-collar criminals with his general theory of differential association (Sutherland 1940, 1945). Contrary to a major group of approaches popular during the late 1930s, Sutherland claimed that the actions of

white-collar criminals were "not correlated with poverty or the psychopathic and sociopathic conditions associated with poverty" (Sutherland 1940, p. 2). Rather, Sutherland argued, white-collar criminals were from the upper-class, were respected and wealthy, and learned about crime through direct or indirect associations with other criminals, and when the situation is considered as more favorable than unfavorable to commit the crime, white-collar criminals commit their crimes (Sutherland 1945).

Control theories help to explain some of the actions of white-collar criminals. Personality traits such as "low self-control" (Piquero et al. 2008) or the "desire for control" (Piquero et al. 2005) can help explain why some people commit crimes. Blickle et al. (2006), for example, found that high-ranking white-collar criminals have low behavioral self-control, high hedonism, high narcissism, and high conscientiousness.

White-collar criminals commit crime because they do not see themselves as criminals and deny their guilt, using inner justifications to do so (Cressey 1953; Benson 1985; Dhami 2007; Sykes and Matza 1957). White-collar criminals do not perceive their actions as criminal; therefore, they find ways to neutralize any feelings of apprehension, justify what they plan to do (Sykes and Matza 1957; Cressey 1953), commit the crime confidently, and deny their guilt (Cressey 1953; Benson 1985). For example, some white-collar criminals see their acts of embezzlement as borrowing from others or a legitimate response to being treated unjustly by their employer (Cressey 1953; see chapters ▶ "Retail Security: Employee Theft" and ▶ "Investigations: Employee Theft of Employer Property" in this encyclopedia). Other white-collar criminals justify their actions by saying that what they did not harm anyone (Dhami 2007) or that they had been set up and were wrongfully convicted or that their actions were justified because everyone was doing the same thing (Benson 1985).

Like control theories, rational choice theories help to explain why white-collar criminals engage in illegal activities. From the perspective of rational choice theories, white-collar criminals calculate their gains and losses before committing their crime (Paternoster and Simpson 1996). A white-collar criminal's decision about whether or not to commit a crime involves the "balancing of both the costs and benefits of offending" and the person's "*perceived* or subjective expectations of reward and cost" (Paternoster and Simpson 1996, p. 553).

Some opportunity theories can be used to explain the actions of white-collar criminals (Benson and Simpson 2009; Bucy et al. 2008). Certain conditions provide an attractive opportunity for a rational perpetrator to commit a white-collar crime. In other words, if the opportunity does not exist, then no crime will be committed. Opportunity theories also hold that regardless of how strong the perpetrator's motivation is to commit a white-collar crime, without the opportunity to act on that motivation, a crime will not be committed (Coleman 1987). Coleman (1987) also connected the opportunity to commit a white-collar crime to cultural influence – namely, the *culture of competition*, which is a natural part of a capitalist society. In such a competitive culture, some white-collar criminals will have more opportunities than other white-collar criminals to commit a crime.

Anomie theory also helps to explain the motives of white-collar criminals. The theory holds that while someone may have socially acceptable and legitimate goals, the absence of any legitimate means to reach those goals leads to deviant behavior. Schoepfer and Piquero (2006), for example, have applied anomie theory to explain embezzlement.

Types and Forms

While classifications of different types of *criminals* do exist in the literature, the classification of white-collar criminal is not among them. The white-collar crime literature focuses more appropriately on *criminality* (i.e., conduct, behavior) rather than on *criminals* (i.e., people). In this regard, one of the most comprehensive typology for white-collar crime is the one developed by Friedrichs (2010, pp. 7–8; see chapters ▶ "Investigations: Bank Fraud" and ▶ "Investigations: Money Laundering" in this encyclopedia).

Friedrichs' typology includes five categories based on criteria such as context, setting, agency, status or position of offender, primary victims, principal form of harm, and legal classification. **Corporate crime** as a type of white-collar crime, for example, refers to the "illegal and harmful acts committed by officers and employees of corporations to promote corporate (and personal) interests." Forms of corporate crime include corporate violence, corporate theft, corporate financial manipulation, and corporate political corruption or meddling. **Occupational crime** as a type of white-collar crime refers to the "illegal or harmful financially driven activity committed within the context of a legitimate, respectable occupation." Forms of occupational crime include retail crime, service crime, crimes of professionals, and employee crime. **Governmental crime** as a type of white-collar crime refers to "a cognate form of white-collar crime; a range of activities wherein government itself, government agencies, government office, or the aspiration to serve in a government office generates illegal or demonstrably harmful acts." Forms of governmental crime include state crime and political white-collar crime. Friedrichs' grouping of **"hybrid" crime** as a type of white-collar crime refers to **state-corporate crime**, **crimes of globalization**, and **high-finance crime**. Hybrid white-collar crimes involve some combination of governmental, corporate, international financial institution, or occupational crime. High-finance crime, for example, refers to "criminal activity in the realm of high-level finance, from banking to securities markets." **Enterprise crime**, **contrepreneurial crime**, **technocrime**, and **avocational crime** refer to what Friedrichs calls **"residual"** type of white-collar crime. Enterprise crime is characterized by the involvement of cooperative enterprises with syndicated (organized) crime and legitimate businesses. Contrepreneurial crime refers to swindles, scams and frauds that are made to look like legitimate businesses. Technocrime refers to the bundling of computers and other high technology with white-collar crime. Avocational crime refers to "illegal but non-conventional criminal acts committed by white collar workers outside a specifically organizational or occupational context, including income tax evasion, insurance fraud, loan/credit fraud, customs evasion, and the purchase of stolen goods."

Consequences and Impact

The 2010 National Public Survey on White Collar Crime shows that "white collar crime significantly affects U.S. citizens" (Huff et al. 2010, p. 22). The impact of white-collar crime can be indiscriminate and widespread, an effect that Moor and Mills (Moore and Mills 1990, p. 410) describe as "democratic." The consequences and impact of white-collar crime, therefore, have the potential to affect society at large, individuals, institutions, and the environment (Bruce and Becker 2007; Katz 2012). Such consequences may be physical, economic, political, societal, and psychological, and they may be long-lasting, large, or small, depending on the situation (Price and Norris 2009; Sutherland 1940, 1945; Shover et al. 1994; Moore and Mills 1990).

The consequences of white-collar crime usually are monetary and/or materialistic. Even in the early twentieth century, one white-collar criminal's financial harm over a year's time could be "six times as much as the annual losses from five hundred burglaries and robberies" of the same stores (Sutherland 1940, p. 5). Consequently, the harm caused by white-collar criminals has the potential to be much greater than the harm caused by conventional criminals (Sutherland 1940, 1945; Huff et al. 2010; Friedrichs 2010). The Association of Certified Fraud Examiners reports that the estimated cost of occupational fraud in 2017 was $4 trillion (ACFE 2018).

The actions of white-collar criminals have a negative effect on people's lives, often leading to "an astronomical toll in deaths, physical health, emotional suffering, and fiscal costs, one that dwarfs comparable losses to street crime" (Shover and Wright 2001, p. 49). For example, the opioid addiction epidemic in USA is claimed to be a result of drug companies' pushing sales and encouraging doctors to prescribe them in spite of the addictive nature of the drugs (Hadland et al.

2019). *The Center for Disease Control and Prevention* (CDC 2019) reports that more than 70,000 people died in 2017 from drug overdoses and about 68 percent of them were involved a prescription or illicit opioid. In an example from the food industry would be that consumers could be "killed by food poisoning, injured by unsafe products, defrauded by unscrupulous sales persons and are daily deceived by descriptions of goods and services" (Croall 2009, p. 130) without knowing that they had been victims of or harmed by white-collar crime.

Because white-collar criminals are highly trusted individuals, a violation of that trust affects social and political institutions. For example, damage to social relationships may lead to social disorganization on a large scale, resulting in a level of societal harm that is far greater than the dollar value of the financial harm (Sutherland 1940). Broken bonds of trust also can lead to the loss of "faith in and support for political institutions, public officials, and governmental processes. Citizens, for the most part, expect public officials to be honest themselves and also to deal unflinchingly with those who employ deceit and exploitation to prey on the public" (Moore and Mills 1990, p. 414). Whether the negative impact of white-collar crime is greater than negative impact of street crime is not known, primarily because white-collar crime is less visible to most people and awareness of such crimes is lower compared with street crime (Friedrichs 2010).

Conclusion

Scholars and practitioners disagree on the definition of the terms *white-collar criminal* and *white-collar crime*, though all can be said to have valid arguments for their views. Friedrichs (1992, p. 16) likens both terms to "a Chinese puzzle." He noted that "whichever way one turns with it new difficulties and conundrums are encountered" and suggests that having a comprehensive definition for both terms might be better than a single standard meaning for both terms (Friedrichs 1992). Without a consensus, debate over the definition of *white-collar criminal* and *white-collar crime* will continue.

White-collar criminals and the offenses they commit should be taken seriously for three reasons. First, white-collar criminals can be difficult to identify from outward appearances. As employees or owners of legitimate businesses or organizations, they work to garner the trust of colleagues and members of the community and then use that bond to conceal their involvement in illegal activity and deflect any suspicion of their involvement in such activity. Second, the consequences of white-collar crimes can be quite serious and widespread. The actions of even one white-collar criminal can affect and harm many people at the same time. The harm can spread from there to social and political institutions and to the environment. Third, the exploitation of technology by white-collar criminals may enable these individuals commit crimes that are not only broader in scope but also much easier to carry out even in younger ages (Payne 2018) than the age groups discussed in this chapter.

Definition

The Commercial Facilities Sector (CFS), one of the 16 critical infrastructure sectors, focuses on predominantly privately owned "sites that draw large crowds of people for shopping, business, entertainment, or lodging," including motion studios, malls, sports arenas, mixed-use facilities, and hotels (Cybersecurity & Infrastructure Security Agency/CISA n.d.).

Introduction

In 2013 the administration of the United States (US; The White House Office of the Press Secretary 2013) released Executive Order (EO) 13636, entitled Improving Critical Infrastructure Cybersecurity (Department of Homeland Security 2013). This EO directed (in part) the executive branch of government to strengthen cybersecurity practices and share cyber threat information (DHS 2013). Additionally, in the same year, the President Obama Administration released the US Presidential Policy Directive 21 (PPD-21). An essential action from the PPD was to require "The U. S. Department of Homeland Security (DHS) to revise the then 2009 National Infrastructure Protection Plan (NIPP) in 240 days from the release date of EO 13636" (DHS, 2013, para 10). The current NIPP issued in 2013 identifies 16 sectors aligned with PPD-21. "The 16 sectors are Chemical, Commercial Facilities, Communications, Critical Manufacturing, Dams, Defense Industrial Base, Emergency Services, Energy, Financial Services, Food and Agriculture, Government Facilities, Healthcare, and Public Health, Information Technology, Nuclear Reactors, Materials, and Waste, Transportation Systems, Water and Wastewater Systems" (CISA 2013, p. 9).

Another critical aspect of EO 13636 is it mandated the development of a cybersecurity framework and for the DHS to establish a voluntary critical infrastructure cybersecurity program. The Framework for Improving Critical Infrastructure Cybersecurity Version 1.0 white paper was released by the National Institute of Standards and Technology (NIST) (NIST, 2014). Unlike other

NIST publications, the FICI white paper focused on the nonfederal government community to manage their cyber risks (NIST 2014). Within the 240 days from the release of EO 13636, the DHS established the Critical Infrastructure Cyber Community C^3 (pronounced "C Cubed") Voluntary Program (C^3VP). "The DHS C^3 VP provides cybersecurity resources to owners and operators of critical infrastructure; small and mid-size businesses; and State, Local, Tribal, and Territorial (SLTT) Governments. Per Executive Order 13636, the C^3 promotes the Cybersecurity Framework, which was developed by the National Institute of Standards and Technology (NIST)" (DHS 2013, p. 4). This program leverages the NIST Cybersecurity Framework, the expertise from academia and business along with state, local, tribal, and territorial (SLTT) government entities (C^3VP).

This entry addresses the Commercial Facilities Sector Plan (CFSP) (CISA 2015b). According to the DHS Critical Infrastructure Resource Center (CIRC), "The Retail Subsector alone generated more than $4.4 trillion in annual sales in 2008" (CIRC n.d., quick Facts). According to the CIRC this sector is divided into eight subsectors. "They are Entertainment and Media, Gaming, Lodging, Outdoor Events, Public Assembly, Real Estate, Retail, and Sports Leagues" (CISA 2015b, p. 3).

The NIST Computer Security Resource Center (CSRC) since the release of EO 13636 has led the cybersecurity doctrine for the CFS. In addition to the issuance of the FICI of 2014, the CSRC and the NIST Computer Science Division (CSD) established the National Cybersecurity Center of Excellence (NCCoE) in 2012 by the NIST in partnership with the State of Maryland and Montgomery County, Md. Although it was created before the release of EO 13636, the NCCoE was and is instrumental in providing cybersecurity doctrinal guidance to the commercial community.

Before the events of the Murrah Building Bombing; the terrorist attack on September 11, 2001; and the circumstances surrounding the response to Hurricane Katrina, there was little doctrinal guidance that identified the needs of the first responder community. Project Responder 5 (PR5) is the fifth iteration in the Project Responder series of studies to articulate the needs of the first responder community (PR5 2017). The initial effort was to "...improve the capabilities of local, state, and federal emergency responders..." (PR3 2014, P 49). Therefore, whether it is physical or cyber, the protection of and the response to Commercial Facilities Sector owners and operators are essential.

The Commercial Facilities Sector Subsectors

In 2015 the Commercial Facilities Sector Plan (CFSP) was released (CISA 2015b). The CFSP outlines eight subsectors that comprise this sector. This sector is overwhelmingly owned and operated by the private sector. As such, these operators must assess and mitigate vulnerabilities to their facilities. The cost to reduce vulnerabilities and to protect them is a funding challenge, particularly as the government has limited decision options as most of these are privately owned and operated. Table 1 shows the eight subsectors of the CFS based on information from CISA (2015b, p. 3). CFS is an important sector to the health and well-being of our way of life and serves as an economic engine for our nation. The CFS and its subsectors rely heavily on other critical infrastructure protection (CIP) sectors. The most critical are emergency services, financial services, energy, communications, healthcare, transportation services, government facilities, food and agriculture, information technology, and water and wastewater treatment sectors (CISA 2015b).

Executive Order (EO) 13636

In Executive Order 13636, titled Improving Critical Infrastructure Cybersecurity (Department of Homeland Security 2013a), the US policy is "to enhance the security and resilience of the Nation's critical infrastructure and to maintain a cyber environment that encourages efficiency, innovation, and economic prosperity while promoting safety, security, business confidentiality, privacy,

Critical Infrastructure: Commercial Facilities Sector, Table 1 Eight subsectors of the Commercial Facilities Sector

1. The *entertainment and media subsector* has approximately 49,000 establishments and represents over $1 trillion of media spend annually.
2. The *gaming subsector* consists of approximately 1,300 casinos and resorts. This subsector contributes over $35 billion in tax revenue.
3. The *lodging subsector* has over 52,500 hotel-/motel-based properties. These facilities generate over $150 billion in annual sales.
4. The *outdoor event subsector* represents over 550 amusement and theme parks. These facilities have approximately 290 million visitors annually.
5. The *retail subsector* has over one million buildings characterized as malls, shopping centers, and retail facilities. This subsector contributes over $2.5 trillion to the US Gross Domestic Product (GDP) annually.
6. The *real estate subsector* consists of over 1 million office buildings, 5.5 million multifamily rentals, and over 48 thousand self-storage facilities. This subsector contributes over $205 billion to the US GDP annually.
7. The *public assembly subsector* has over 124, 500 establishments characterized as stadiums, arenas, theaters, and cultural properties. These facilities in some cases share responsibilities with the sports league subsector. This subsector activity is a National Special Security Event (NSSE). An NSSE is an event that DHS has considered as critical in that it would be susceptible to a terrorist attack or criminal activity. NSSE has national and international significance. Events such as the US Presidential Democrat and Republican national conventions held in public assembly sector arenas qualify as an NSSE. The United States Secret Service releases an Annual Report. The latest report is the Office of Protective Operations 2017 Annual eport (CMR 2017). The United States Secret Service is the lead agency in charge of the planning, coordination, and implementation of security operations for the event (CMR 2017).
8. The *sports league subsector* like the public assembly subsector has one NSSE event. Each year the National Football Leagues "Super Bowl" is designated as an NSSE event. The NSSE designation aside, the subsector sports industry contributes over $480 billion annually.

and civil liberties" (EO 13636, Sect. 4 (a)). In enacting this policy, the EO required NIST to develop a voluntary risk-based Cybersecurity Framework. The resulting framework is a "…set of industry standards and best practices to help organizations manage cybersecurity risks…" (NIST Cybersecurity Framework 2014 p. 1). The resulting cybersecurity framework was created through a collaboration between NIST and the private sector and uses a common language to address and cost-effectively manage cybersecurity risk based on business needs without placing additional regulatory requirements on businesses.

National Infrastructure Protection Plan

The evolution of the US National Infrastructure Protection Plan (NIPP) sector program was documented by John D. Moteff, a specialist in the science and technology policy office of the Congressional Research Service (CRS). The first NIPP identified 17 sectors aligned with Homeland Security Presidential Directive 7 (HSPD-7). The next NIPP identified 18 sectors also aligned with HSPD-7 (CISA 2013). The EO 13636, titled Improving Critical Infrastructure Cybersecurity, issued and directed (in part) the executive branch of government to strengthen cybersecurity practices and share cyber threat information. The US Presidential Policy Directive 21 (PPD-21) established the 16 critical infrastructure sectors and aligned them with a federal government agency. These agencies are referred to as sector-specific agencies, (SSA), (CRS R42683) and (CRS RL30153).

The importance of the NIPP to all of the CIP sectors is it provides a framework for each sector to develop their visions, mission, and goals. In 2009, the framework had an element or chevron titled "Prioritize". Note the NIPP refers to each step of the risk management framework as chevrons (CISA 2013, Sect. 5, p. 15). Through the use of a critical infrastructure risk management framework, the NIPP lays out a protocol that establishes an information sharing environment (CISA 2013). A significant contribution is the establishment of a critical infrastructure risk management framework. The framework was amended in 2013, resulting in the removal of this chevron (CISA

Critical Infrastructure: Commercial Facilities Sector, Table 2 CFS goals and priorities of CFSP (CFSP 2015, Executive Summary, p. vi)

	Goals	Priorities
1	Strengthen trusted and protected sharing of information	"A" to improve information sharing; "B" the value of sector partnerships
2	Support the sector's needs for open access, public confidence, and economic vitality	"C" to expand training and exercises "D" to improve cybersecurity awareness
3	Increase capabilities and maintain advanced planning	"E" to enhance coordination
4	Assess and analyze threats, vulnerabilities, and consequences using the equation commonly referred to by NIST is risk = threat x vulnerability x consequence (Rochford Security Update 2017)	"F" to continue cyber and physical risk assessments
5	Promote continuous learning	"G" to facilitate information sharing of best practices for risk mitigation activities

2013, Sect. 5, p. 15). The 2013 NIPP recognized that each sector would have different priorities. As in the 2009 version of the NIPP, each chevron was required to address the three elements of the framework – physical, cyber, and human (CISA 2013, Sect 5, p. 15). These elements according to the NIPP should be integrated within each chevron, as appropriate.

A summary of the five chevrons indicates the general guidance the NIPP provides to the sectors. The first chevron is to set goals and objectives. This chevron requires the identification of specific critical infrastructure that is at risk (CISA 2013, Sect. 5, p. 16). Table 2 shows the CFS outline of the five goals of the CFS SSP (CISA 2015b) and their priorities. Finally, the sector mapped out 25 sector activities that align with and map to the goals and their corresponding priority.

The second chevron is to identify infrastructure. Here the sectors must identify assets, systems, networks, and sector interdependencies (CISA 2013, Sect. 5, pp. 16–17). DHS (2013c) assists the sector through the Protective Security Advisor (PSA) Program by providing "a robust operational field capability, with Regional Directors (RDs) and PSAs serving in 73 districts in 50 States and Puerto Rico" (DHS PSA Fact Sheet 2014).

The RDs and PSAs serve as the link to the Department of Homeland Security (DHS) infrastructure protection resources. The PSAs have five mission areas that directly support the protection of critical infrastructure:

- Plan, coordinate, and conduct security surveys and assessments – PSAs conduct voluntary, non-regulatory security surveys and assessments on critical infrastructure assets and facilities within their respective regions.
- Plan and conduct outreach activities – PSAs conduct outreach activities with critical infrastructure owners and operators, community groups, and faith-based organizations in support of IP priorities.
- Support National Special Security Events (NSSEs) and Special Event Activity Rating (SEAR) events – PSAs support Federal, State, and local officials responsible for planning, leading, and coordinating NSSE and SEAR events.
- Respond to incidents – PSAs plan for and, when directed, deploy to Unified Area Command Groups, Joint Operations Centers, Federal Emergency Management Agency Regional Response Coordination Centers, and/or State and local Emergency Operations Centers in response to natural or man-made incidents.
- Coordinate and support improvised explosive device awareness and risk mitigation training. (DHS 2014, PSA Fact sheet, page 1).

They assist with and support National Special Security Events (NSSEs) and respond to incidents. Finally, they coordinate and support improvised explosive device awareness and risk mitigation training (CISA Protective Security Advisor Program).

The third chevron is to assess and analyze risks. Risks are characterized as threats, vulnerabilities, and consequences. The organization owning or operating the infrastructure should develop risk scenarios where events could be assessed in terms of their threat, vulnerabilities, and impacts to the continuity of the enterprise (CISA 2013, Sect. 5, pp. 17–18). As previously mentioned, the DHS PSA Program may assist the sector. The PSAs can come at no cost to the stakeholder. The advisor will use the computer-based assessment tool or CBAT and the infrastructure survey tool or IST to provide the stakeholder with a detailed assessment report (CFS SSP 2015b, Sect. 3.1, pp. 21–22).

The fourth chevron requires the company to implement risk management activities. The stakeholder exercises the process to identify, deter, detect, disrupt, and prepare for threats and hazards. The infrastructure managers attempt to reduce their vulnerabilities and minimize their exposure to adverse consequences. NIPP recommends that critical infrastructure stakeholders prepare their infrastructure to become resilient. This circumstance means that there must be a responsible response to events along with the ability to recover (CISA 2013, Sect. 5, pp. 18–20). In response, the CFSP provides that stakeholders participate in various information sharing activities. The subsector participants establish security alliance councils to engage in cross-sector and subsector principals.

Two essential programs will assist the sector with this information sharing program. The first is the InfraGard program. "InfraGard is a partnership between the FBI and members of the private sector. The InfraGard program provides a vehicle for seamless public-private collaboration with government that expedites the timely exchange of information and promotes mutual learning opportunities relevant to the protection of Critical Infrastructure" (retrieved from InfraGard homepage on May 5, 2019, para 1). The second initiative is the DHS SAFETY Act Program. "As part of the Homeland Security Act of 2002, Public Law 107-296, Congress enacted the Support Anti-Terrorism by Fostering Effective Technologies Act (SAFETY Act) of 2002" (DHS S&T 2016, para 1). The SAFETY Act provides incentives for the development and deployment of anti-terrorism technologies by creating systems of risk and litigation management. The purpose of the Act is to ensure that the threat of liability does not deter potential manufacturers or sellers of effective anti-terrorism technologies from developing and commercializing technologies that could save lives (DHS S&T 2016, para 2). The CFSP has a priority for members of the sector to participate in this program and use technologies that are SAFETY Act designated or certified (CFS SSP 2015b, Sect. 3.1, pp. 21–22).

The fifth NIPP risk management framework chevron is measuring effectiveness. The NIPP requires sector stakeholders to evaluate achievement of goals, learn, and adapt during and after exercises and incidents (CISA 2013, Sect. 5, p. 20). To measure the effectiveness of the CFS activities, the CFSP outlined 25 activities with expected metrics. As mentioned earlier in this article, each CFS activity has one or more priority designations (CFS SSP 2015b Sect. 4.1, pp. 28–29) Also the CFSP Appendix B provides a chart that depicts alignment with the NIPP 2013 call-to-action imperatives. Appendix C outlines Sector-Specific Tabletop Exercise Programs (SSTEP) and Independent Study courses, publications, and tools such as the cybersecurity evaluation program and cyber resilience review. For those stakeholders involved with industrial control systems (ISC), the ICS Cyber Emergency Response Team (ISC-CERT) makes available the cybersecurity evaluation tool (CSET) (CFS SSP 2015b Appendices B and C, pp. 36–44).

National Institute of Standards and Technology

The National Institute of Standards and Technology (NIST), as a partner with the Small Business Administration and the Federal Bureau of Investigation in an information security awareness outreach to the small business community, provides publications and information to assist

commercial enterprises with their cybersecurity initiatives. Many commercial enterprises do not place a high priority on cybersecurity. The security of client and customer information, systems, and networks takes a backseat to the operation of the business. However, their customers, employees, and trading partners' cybersecurity and the protection of their personal information are imperative.

To better address these risks, NIST publishes documents to inform and educate the business community on cybersecurity policies and best practices. Additionally, NIST established the National Cybersecurity Center of Excellence (NCCoE). The NCCoE was established in 2012 by NIST in partnership with the State of Maryland and Montgomery County, Md. NCCoE is a collaborative hub where industry organizations, government, and academic institutions collaborate. This collaboration addresses cybersecurity issues. This program is an important public-private partnership. NCCoE enables the creation of practical cybersecurity solutions for specific industries, as well as for broad, cross-sector technology challenges. For example, the NCCoE Consumer and Retail Sector is one area of the center's key initiatives. The work of this initiative concentrated on consumer-facing businesses cybersecurity posture. Other programs or use cases are financial services sector, health information technology sector, hospitality sector, manufacturing sector, energy sector, transportation sector, public safety, and first responder sector. These projects of the NCCoE are aligned closely with the critical infrastructure sectors. The key emphasis is to enhance the cybersecurity posture of the CFS (NCCoE 2012).

Critical Infrastructure Cyber Community Voluntary Program C^3

EO 13636 required NIST to develop and publish a voluntary risk-based Cybersecurity Framework. The EO also required DHS to develop cybersecurity information to small and midsize businesses. Thus, the Critical Infrastructure Cyber Community Voluntary Program C^3 (C^3VP) was released on February 12, 2014 (DHS 2014). This program supports the NIST Cybersecurity Framework. The key initiative of this program is the Cyber Resilience Review (CRR). This resilience review is a process improvement model where stakeholders could self-assess their organization's current state of cybersecurity preparedness. The Cyber Resilience Review evaluates capabilities across ten domains. These domains are "asset management, control management, configuration and change management, vulnerability management, incident management, service continuity management, risk management, external dependency management, situational awareness training and awareness" (CRR 2014). The CFS SSP recommends the use of the Cyber Resilience Review as a tool for managing cyber risks (CFS SSP 2015b, Sect. 3.2, pp. 23–24). It is important that a cross-functional team within an organization participate with this review. Members from the chief security office, information technology, operations, and disaster recovery organizational elements participate. This list is not all-inclusive. Organizations may opt to include human resources, financial management, and facility management (CRR 2014). The Cyber Resilience Review is an inclusive process versus an exclusive program. This process invites all stakeholders to provide input to the review's analytical process.

Critical Infrastructure Response

A key component of business sustainability, continuity, and recovery is the emergency response environment. The DHS Science and Technology Directorate has funded and supported Project Responder 5 (PR5 2007). The PR5 report is a report of the examination of the response based on the current threat environment, the responder capabilities, and the application of available technological resources.

Therefore, the PR5 report provides a substantial nexus to the CFS. Homeland Security Presidential Directive 8 defines a first responder as "The term 'first responder' refers to those individuals who in the early stages of an incident are responsible for the protection and preservation of life, property, evidence, and the environment, including emergency response providers as defined in section 2 of the Homeland Security Act of 2002" (6 U.S.C. § 101), as well as emergency management, public health, clinical care, public works, and other skilled support personnel (such as equipment operators) that provide immediate support services during prevention, response, and recovery operations" (HSPD-8 2003 para 2 (d)).

The PR5 report describes 37 capabilities of needs encountered by first responders grouped into 9 areas. These include "1. risk assessment and planning, 2. communication and information sharing, 3. command, control and coordination, 4. situational awareness, 5. training and exercise, 6. casualty management, 7. Responder health and safety, 8. Intelligence and investigation, and 9. Logistics and resource management" (PR5 2017 Fig. 8. PR5 capability needs p. 25). The response to incidents incurred by stakeholders of the CFS is critical to the survivability of sector organizations. Therefore, there is an increased need for the CFS to establish an active information sharing program with first responders.

Conclusion

Before the promulgation of the CIP program and the release of the CFS SSP, the preponderance of commercial sector protection initiated was a state and local responsibility. The diversity of the CFS and myriad of threats presented a unique challenge to the stakeholders of the sector. To rise to the challenges, the CFS provides an actual government and private sector collaboration. In the CFS SSP, the commercial enterprises have the governance to develop plans and programs to protect their resources. The openness of sector facilities presents serious vulnerabilities. This unencumbered access to the sector facilities present challenges to the first responder community. EO 13636 required DHS and NIST to issue governance. NIST published the Framework for Improving Critical Infrastructure Cybersecurity. DHS established the Critical Infrastructure Cyber Community Voluntary Program C^3 to enhance the CFS stakeholder's ability to evaluate their resilience posture. The Cyber Resilience Review is a process improvement model where stakeholders could self-assess their organization's current state of preparedness.

Additionally, DHS, through the release of Project Responder 5 report, identified 37 capabilities of first responder needs, grouped into 9 areas. This effort provided a substantial nexus between the federal government, the stakeholders of the CFS, and the first responders tasked with the responsibility to protect the nation. With the continuing threat to the sector's cyber infrastructure, NIST has partnered with the Small Business Administration and the Federal Bureau of Investigation to publish the NIST Interagency Report titled Small Business Information Security: The Fundamentals. These reports, as well as the collaboration between government and private industry through the InfraGard program, will provide a vital conduit to mitigate future challenges.

Keywords

Dependencies · Infrastructure concentration · Interdependencies · Risk · Supply chains

Definition

Critical Infrastructure	"Systems and assets, whether physical or virtual, so vital to the United States that the incapacity or destruction of such systems and assets would have a debilitating impact on security, national economic security, national public health or safety, or any combination of those matters" (Uniting and Strengthening America by Providing Appropriate Tools Required to Intercept and Obstruct Terrorism [USA PATRIOT] Act, 2001, § 1016).
Critical Manufacturing Sector	Privately owned and operated assets (manufacturing plants, logistical distribution facilities, storage facilities, and center business offices) that convert raw materials and manufactures specialized materials and equipment vital to the construction, electrical, defense, and industries among others (U.S. Department of Homeland Security [DHS] 2015a).

Introduction

The Critical Manufacturing Sector (CMS) is just one of many critical infrastructure sectors that play an important role in support of a democratic nation and help to ensure US economic vitality and national security. However, the CMS is not immune to challenges as supply chain disruptions at the national and global levels can induce severe consequences (Executive Office of the President 2017). These high-level challenges are just the beginning as the CMS faces a myriad of risks (natural hazards, technological hazards, and human-caused incidents) and cross-sector dependencies, which can result in significant cascading effects.

The remainder of this entry provides a general overview of the CMS to enable a general understanding. Within the discussion, key operational characteristics of the CMS are reviewed along with a description of the current threat and hazard picture to include critical cross-sector dependencies. This discussion will also include mission, goals, and priorities of the CMS along with the partnership structure. Partnerships and information sharing within the CMS are elevated due to a high private ownership share of sector assets. Overall, this entry provides a basic understanding of the CMS to enable critical evaluation of current policies, practices, and needed activities to address gaps in security and resilience.

Sector Overview

The CMS consists of the manufacturing industries which have significant national economic implications and are considered crucial for operations within other infrastructure sectors. The main activities of the CMS are to process and manufacture. Processing involves converting raw materials and primary metals into useable products that are subsequently utilized in manufacturing. Specific manufacturing that is deemed critical includes machinery (engine, turbines, power-transmission, heavy machinery), electrical components (motors, transformers, generators), and transportation (for surface, water, and rail modes). Further, the CMS produces highly specialized parts and equipment essential to specific US industries, particularly the Defense Industrial Base Sector. Additionally, the CMS produces the backbone materials and components for the Energy Sector and Transportation Systems Sector. Therefore, failures and/or disruptions in the CMS can cause severe consequences in terms of economic impact and cascading effects to other infrastructure sectors. Lastly, the US economic prosperity and continuity are dependent on the CMS, and this sector's production comprises 12 percent of the nation's gross domestic product (GDP) and employs approximately 12 million individuals.

Sector Components and Assets

Due to the diversity of manufacturers and high private ownership share, the CMS is organized into four subsectors based on functions and operations. Regardless of subsector, facilities (manufacturing, processing, and distribution), offices (sales and headquarters), and product storage are included as key assets. Characteristics of each subsector are provided below per the *Critical Manufacturing Sector-Specific Plan* (CM SSP).

Primary Metals Manufacturing: Converts raw materials into assemblies, intermediate products, and end products. These products can include sheet metal, bar stock, I-beams, slabs, or pipes. Processes aluminum, iron, and steel that supports transportation, urban centers, energy supply, clean water, safe food, and defense. There are 4,556 manufacturers in this subsector.

Machinery Manufacturing: Produces engines, turbines, and power-transmission equipment. Products support infrastructure and primary operations in a number of critical US industries. Includes heavy-equipment manufacturing. There are 24,124 manufacturers in this subsector.

Electrical Equipment, Appliance, and Component Manufacturing: Produces specialized equipment, assemblies, intermediate products, and end products for power generation.

These products include transformers, electric motors and generators, and industrial controls. There are 5,765 manufacturers in this subsector.

Transportation Manufacturing: Produces cars and trucks, aircraft and component parts, aerospace products and parts, railroad cars and other railroad products, and other transportation equipment. There are 11,814 manufacturers in this subsector. (DHS 2015a, p. 4).

Key Sector Operating Characteristics

The importance of the CMS can be summed in one specific figure: CMS produces 60% of all of US exports. Facilities, employees, suppliers, and customers around the world are part of the complex international, interdependent networks of raw materials and finished products in which CMS assets operate. Although it improves production agility, this complex global network increases the exposure of the CMS to a myriad of risks and conditions. In fact, disruptions in supply chains are one of the top security and resilience concerns of the CMS. This is because present supply chains focus on efficiency (e.g., lean inventories) and just-in-time practices, but this also increases vulnerability of CMS assets to long-term disruptions. This is because CMS assets are part of the network that links suppliers, vendors, partners, integrators, contractors, and customers not only to their asset, but also to other industries and businesses. Therefore, CMS assets must ensure resilience against supply chain disruptions, which includes constant monitoring and a proactive stance to mitigate any disruptions.

Sector-Specific Agency

The US government by itself cannot create a secure and resilient CMS, especially in relation to high private sector ownership. Rather, the end goal requires a dedicated whole-of-nation approach involving public and private stakeholders. Leading this whole-of-nation approach is the designated Sector-Specific Agency (SSA) as defined in *Presidential Policy Directive (PPD) 21: Critical Infrastructure Security and Resilience* (Executive Office of the President 2013). The designated SSA for the CMS is DHS. More specifically, the Office of Infrastructure Protection is the delegated responsible entity within DHS.

Sector Partnerships

The *National Infrastructure Protection Plan* (NIPP) defines a partnership structure for the infrastructure sectors that is facilitated through Government Coordinating Councils (GCCs) and Sector Coordinating Councils (SCCs). The SCCs are comprised of owners and operators and enable them to work directly with one another. Typically organized under subsectors within an overall infrastructure sector, SCCs are self-organized, self-run, and self-governed councils consisting of owners and operators and their representatives and serve as principal collaboration points between the GCCs and the SSAs. As for the GCCs, SSAs work closely with state, local, tribal, and territorial (SLTT) agencies through the GCCs to enable sharing of actionable, relevant risk information; exchanging of best practices; building of cross-sector situational awareness; and enabling risk-informed decision-making.

The importance of SLTT agencies is illustrated by the fact they work in close proximity to the owners or operators of the CMS. Coordination with SLTT agencies is imperative as all incidents start local and these agencies are first to respond to any incident. Therefore, SLTT agencies provide important local capability to include mutual aid agreements and communication plans where appropriate. It is the responsibility of the SSA to cultivate relationships and information sharing between SLTT agencies and the GCCs and SCCs to enhance situational awareness and addresses identified risks to the CMS. This illustrates that the success of a sector's partnership model depends on the ability to leverage knowledge, capabilities, and resources through GCC and SCC activities. Through this collaboration exchange, owners and operators of CMS assets can better understand risks and interdependencies

and develop appropriate security and resilience strategies to mitigate identified risks.

Sector Risks

Despite the diverse collection of assets within the CMS, common risks exist that each sector must address. Natural disasters, active shooters, and terrorist threats are persistent risks across the CMS as well as geopolitical events due to its linkage to a global supply chain (DHS 2014). Further, cyber attacks risks continue to grow as reliance on networked systems continues to rise. This illustrates the need to comprehensively examine risks across the CMS through existing partnership structures in an effort to ensure security and resilience. Although numerous risks can be discussed, the following sections focus on those risks deemed significant. It is acknowledged there are other significant risks to the CMS, but these risks will not be discussed for the sake of brevity. Expanded information on risks to the CMS is accessible via the CM SSP.

Concentration

Within the CMS, geographic concentration helps to reduce overall costs due to a localization of expertise and reduction in logistical operations. However, this concentration can increase vulnerability to geographic risks and local disasters that can produce cascading effects (Parfomak 2008). Although the CMS is widely dispersed across the nation, certain subsectors or aspects are concentrated in specific regions, which require additional security and resilience activities. For example, CMS facilities are geographically concentrated around coastal ports (Parfomak 2008). This placement supports the importing and exporting logistics of materials and products within the sector. Further, the global supply chain also converges in strategic geographic areas thereby creating chokepoints that can cause and magnify disruptions. This is especially relevant to global maritime transportation in areas such as the Malaccan Strait (Indian Ocean), Gulf of Hormuz (Middle East), and the Panama Canal (links Atlantic and Pacific Oceans). However, disruption in access to rare and and/or scarce raw materials may also create vulnerabilities. Therefore, global networks must be constantly monitored in order to anticipate, respond to, and mitigate possible disruptions.

Natural Hazards, Climate Change, and Extreme Weather

Natural hazards are a constant threat to all critical infrastructure sectors. Severe storms, hurricanes, earthquakes, tornadoes, volcanoes, drought, floods, landslides, tsunamis, and wildfires can cause significant property and economic damage, threaten safety of employees and facilities, and restrict access to critical resources such as power, water, transportation, and food supplies. Natural threats are typically present in defined geographic areas thereby increasing the vulnerability of physical assets and employees in those areas. Specific natural threats that can affect the CSM both domestically and globally should be identified according to likelihood of occurrence. Global weather is important as well in the CMS because natural disasters in other global regions can result in cascading disruptions in supply chains. This is in addition to natural disasters interrupting critical dependent sector services (e.g., Energy Sector) resulting in delays or shutdowns.

Today, the risk of natural hazards is increasing due to climate change. Although it occurs gradually over time, impacts from climate change are presently viewable and are projected to worsen in the future. In fact, the CMS is already impacted by climate change both in the United States and globally. This has led to both DHS and the US Department of Defense (DOD) to view climate change as a threat multiplier. Natural hazards and extreme weather result in risks such as power interruptions, wildfires, regional flooding, droughts, and severe storms, and each carries its own consequences to CMS assets. However, climate change has made extreme weather events more frequent and intense.

Therefore, climate change has altered the frequency and intensity of natural hazards and severe weather, which can produce significant cascading effects on the CMS. For example, the Energy Sector can be stressed through extreme heat and diminished precipitation thereby causing possible power interruptions to CMS assets. Further, sea-level rise accompanied by storm surge increases coastal flooding, which impacts CMS assets geographically concentrated in coastal areas. An example of this is the impact on shipbuilding operations in the Newport News and Norfolk (VA) area (Parfomak 2008). Therefore, actions related to risk assessment, mitigation, resilience, and adaptation must include climate change in addition to natural hazards and severe weather. If not, historical examples provide poignant examples of how the CMS has been affected significantly by climate-related hazards.

Active Shooter/Armed Attacker

The DHS Interagency Security Committee (ICS) defines an active shooter as "an individual or individuals actively engaged in killing or attempting to kill people in a populated area" (Interagency Security Committee 2015, p. 1). Although a firearm is the most common weapon used in active shooter/armed attacker events, other weapons – knives, bats, etc. – can be utilized to harm innocent individuals. Active shooter events pose significant challenges to all CMS assets (such as workplace violence) as the incidents do not follow a specific pattern or a method to the selection of victims. Therefore, active shooter incidents are sometimes impossible to predict and/or prevent. This is further complicated by the fact that active shooter incidents require less resources and planning than other attack methodologies, such as an explosive attack. The frequency of active shooter incidents has increased over the past several years, and incidents have occurred at numerous CMS assets.

As illustrated in previous events, active shooter incidents quickly evolve and are dynamic. Virtually all active shooter incidents end via force by responding law enforcement agencies or through suicide by the assailant. Therefore, CMS assets and on-site individuals must be prepared to address and mitigate an active shooter incident prior to arrival of law enforcement resources. This preparedness can be in the form of security protocols as well as ensuring employees are trained both mentally and physically to deal with an active shooter situation. Overall, recent events illustrate the need to reduce the risk of active shooter incidents to include ongoing preparedness and strengthening of prevention and protection efforts.

Cyber Attacks

Adversaries have successfully executed cyber attacks against the CMS over the past several years (Bennett 2016). These attacks have released unimaginable amounts of private and confidential data and have resulted in damages in excessive of hundreds of millions of dollars. Cyber attacks do not only come from sole individuals or groups but also from state-sponsored activities from countries such as Russia, China, and North Korea. This has led to an increase in hacktivism or politically motivated cyber attacks. Another area of concern related to cyber attacks is the increasing use of comprehensive, computerized building management systems, which control heating, ventilation, and air conditioning (HVAC) systems, access control systems, surveillance systems, etc. These systems reside on networks which makes them vulnerable to a cyber attack or a significant network outage. Of particular importance is the possibility of a cyber attack leading to local or system-wide outages resulting in the loss of ability to control physical access, lighting, temperature, or even life-safety systems.

The more significant danger of cyber attacks in the CMS is intrusion into industrial control systems (ICS) and supervisory control and data acquisition (SCADA) systems. Unauthorized intrusion into these systems has the potential to result in severe negative impacts to the

CMS asset that could cascade and create impacts in other sectors dependent on specific production provided by the CMS. As such, the cyber risk has been recognized by the CMS as a high-priority concern (DHS 2015b; Government Accountability Office 2015). In response to the cyber risk, CMS owners/operators can follow cybersecurity implementation framework guidance detailed in the *Framework for Improving Critical Infrastructure Cybersecurity* developed by the National Institute of Standards and Technology (NIST 2015).

The recognition and focus on cyber attacks are important due to recent successful, high-profile cyber attacks in the CMS. In fact, the US Computer Emergency Response Team (2017) has reported that threat actors are increasingly targeting assets within the CMS through the use of "open-source reconnaissance, spear-phishing emails (from compromised legitimate accounts), watering-hole domains, host-based exploitation, and ongoing credential gathering" (p. 1). Further, the number of investigations into cyber attacks by DHS increases each year, in which most attacks are related to spear-phishing campaigns. The increasing reliance on computer networks for operations as well as security presents increased risk of cyber attacks by individual external (hacktivists) and internal (sabotage by former employees) to the CMS.

Terrorism and Violent Extremism

Certain characteristics of the CMS increase the target attractiveness to a potential terrorist or violent extremist. As such, the threats of attack from terrorists and violent extremists are major contributors to the risk profiles of the CMS. Overall, the CMS represents attractive targets to both domestic and international terrorist groups as well as violent extremists. Therefore, the CMS must be cognizant of the changing domestic and international terrorist threats, including the threat from homegrown violent extremists (HVEs). Some counterterrorism experts consider HVEs as the most immediate threat to US infrastructure. One of the reasons is that HVEs can be US citizens or legal permanent residents, which enables them to freely operate throughout US society. This increases the risk of insider threats in which radicalized individuals who work in the CMS can exploit vulnerabilities through their inside knowledge. However, HVEs typically have less access to resources and training, which results in their planning and attack methodology being simpler and less technical. This asymmetric threat presents challenges in predicting and interdicting attack plots.

Unmanned Aircraft Systems

Unmanned aircraft systems (UAS) are an emerging threat to the CMS. The increased use of UAS throughout the Nation is a serious concern due to the ability to use them to cause damage to persons and property (Coullahan 2017). UAS are particularly worrisome to CMS assets because they enable individuals to access restricted and previously unreachable areas, such as the air space above a facility. The ability to access this space could provide opportunities to cause significant damage or casualties. Further, adversaries can utilize UAS to obtain information about a facility – security layouts – thereby providing highly valuable information for planning and executing an attack.

Supply Chain Disruptions

As previously discussed, today's global supply chain is optimized for productivity and efficiency. Therefore, disruptions in the supply chain can quickly cause cascading effects especially if raw materials cannot reach CMS assets. An absence of raw materials will also cause the inability to manufacture and deliver finished products. Disruptions in the global supply chain are the result of one or many causes, including civil unrest and natural disasters. Technology also plays a role as the Maritime Transportation System (MTS) is dependent on Global

Positioning Systems (GPS) and resulting positioning, navigation, and timing data. Disruptions in the ability to obtain GPS data through either unintentional or intentional (cyber attack) means have the potential to create significant cascading supply chain disruptions. Therefore, CMS assets must be able to withstand infrequent, yet high-impact risks related to the global supply chain.

Global Political and Social Implications

One important aspect of the US supply chain is that CMS assets are now more dependent on raw materials and minerals from foreign countries due to declining mining activity in the United States. This is in addition to CMS assets utilizing foreign markets to reduce overall costs related to component manufacturing, equipment, machinery, and labor. This dependence on international networks increases risk for CMS assets to a host of global risks. In addition to the global supply chain, the CMS must now keep abreast of global attitudes toward the United States, geopolitical unrest, economic conditions, and other risk factors associated with global markets. These risk and variables impact foreign operations, global supply chain providers, and raw material access and can result in significant cascading disruptions.

Primary Sector Dependencies and Interdependencies

Today, the US critical infrastructure sectors are highly dependent and interdependent on one another through physical and cyber linkages. After a natural disaster, man-made incident, or technological accident, a significant failure in one sector – such as in the Energy Sector or Water and Wastewater Systems Sector – has the potential to cascade and create significant impacts to other regions. Currently, the CMS has interdependencies with the sectors of Communications and Information Technology, and dependencies on the sectors of Chemical, Energy, Financial, Transportation Systems, and Water and Wastewater (DHS 2014, 2015a). Descriptions of select dependencies and independencies are provided below.

Energy: Provides power, which supports CMS functions. This is the primary dependency for the CMS. Without power, CMS assets cannot not function for an extended period of time, as access to backup power is often limited in scope. An interruption to the power supply would directly impact all CMS assets located in the affected electrical service region and could have cascading effects on other sectors.

Water and Wastewater Systems: Provides a supply of potable water and handles the treatment of wastewater. In some cases, continuous water sources are essential for critical manufacturing processes. Without these services, CMS assets would be forced to be shut down until services are restored.

Transportation Systems: Transportation systems allow employees and customers to travel to and from CMS assets to receive products and supplies. Manufacturers depend on multiple modes of transportation (aviation, freight rail, highway, and maritime) for the secure movement of raw materials and finished products.

Financial Services: Provides financial services to enable CMS assets to conduct daily business operations.

Communications: CMS asset owners and operators rely on the Communications Sector for telecommunications access for operations and logistics.

Information Technology: Enables day-to-day operations and financial transactions. Underpins supply chain coordination and control system processes.

Chemical: A consistent supply of a range of chemicals is required in multiple CMS processes (DHS 2015a, p. 3, 6–7).

In addition to external dependencies and interdependencies between sectors, the CMS also experiences internal interdependencies similar to other infrastructure sectors. For example, CMS assets engaging in Machinery Manufacturing is dependent on products from Primary Metals Manufacturing assets.

However, Primary Metals Manufacturing assets are also dependent on Machinery Manufacturing assets to produce machinery and parts to enable raw material processing. Therefore, interdependency in this example is a two-way street relationship.

Today, the continual operation of the CMS is dependent and interdependent on other infrastructure sectors similar to those sectors that are interdependent with the CMS. Greater dependences and interdependencies, especially in the cyber realm related to communications and information technology, create the potential that even a localized disruption will have the ability to cascade to numerous CMS assets. This is in addition to the vulnerabilities within the global and national supply chains that can pose significant disruptions to the CMS.

Sector Mission, Goals, and Priorities

In alignment with the NIPP, each SSA develops a specific mission for their respective infrastructure sector, which is defined in individual SSPs. Listed below is the specific mission statement for the CMS.

Mission Statement: Strengthen the security and resilience of the Critical Manufacturing Sector by building an active public-private partnership to coordinate efforts that enable proactive risk reduction and effective response, recovery, and adaptation (DHS 2015a, p. 15).

In addition to defining the mission, the CM SSP identifies specific goals and priorities, which are aligned with the five overall national goals defined in the NIPP.

Sector Goals

1. Improve information sharing and promote continuous learning. *(NIPP Goal #4).*
2. Identify sector-specific risks. *(NIPP Goal #1).*
3. Develop cost-effective strategies to reduce risks. *(NIPP Goal #2).*
4. Support research and development efforts and advanced planning to ensure rapid response and recovery. *(NIPP Goals #3 and #5)* (DHS 2015a, p. 15).

Sector Priorities

1. Evaluating interdependencies with other sectors and within supply chains.
2. Increasing engagement and collaboration both within the sector and with other critical infrastructure sectors.
3. Raising risk awareness at executive levels.
4. Improving cybersecurity knowledge, tools, capabilities, and practices.
5. Participating in cross-sector trainings and exercises to improve response and recovery. (DHS 2015a, p. 15).

Conclusion

As with all US infrastructure sectors, the CMS is vitally important to individuals, communities, and the nation overall. Another important aspect of the CMS is that it helps preserve the American way of life. For example, the CMS not only supports employment but also manufactures military equipment utilized to defend US national security. However, significant risks to security and resilience of the CMS continue to evolve. These risks include actions happening on the world stage as well as actions within numerous dependent and interdependent sectors. These risks must be addressed as the CMS is a critical contributor to US national security and economic vitality.

Keywords

Critical infrastructure · Defense industrial base sector

Definition

The Critical Infrastructures Protection Act of 2001 (42 U.S.C. 5195c (e)) (GPO 2010) defines critical infrastructure as "systems and assets, whether physical or virtual, so vital to the United States that the incapacity or destruction of such systems and assets would have a debilitating impact on security, national economic security, national public health or safety, or any combination of those matters."

The US Department of Homeland Security (DHS 2019a) defines the defense industrial base sector as "the worldwide industrial complex that enables research and development, as well as design, production, delivery, and maintenance of military weapons systems, subsystems, and components or parts, to meet US military requirements." This sector is one of the 16 critical infrastructure sectors vital to the United States.

Introduction

Former US President Barack Obama issued the Presidential Policy Directive PPD-21 in Feb 2013 (PPD-21 2013). The subject of the directive was critical infrastructure security and resilience. This directive revoked an earlier directive viz. the Homeland Security Presidential Directive/HSPD-7. PPD-21 identified 16 critical infrastructure sectors. One of these sectors is the defense industrial base (DIB) sector which is focused here.

The key objective of PPD-21 (PPD-21 2013) was to fortify and preserve "secure, functioning, and resilient critical infrastructure." The term critical infrastructure has already been defined earlier under Definitions. PPD-21 defined the terms secure and resilience. According to PPD-21 (PPD-21 2013), the term secure refers to "reducing the risk to critical infrastructure by physical means or defense cyber measures to intrusions, attacks, or the effects of natural or manmade disasters." The term resilience means "the ability to prepare for and adapt to changing conditions and withstand and recover rapidly from disruptions. Resilience includes the ability to withstand and recover from deliberate attacks, accidents, or naturally occurring threats or incidents" (PPD-21).

The DIB sector is a critical infrastructure sector, hence it becomes necessary to fortify and preserve it as stipulated by PPD-21.

Sector Overview

The Defense Industrial Base (DIB) sector supplies goods and services that are indispensable to US military operations (DHS 2019a). This sector accommodates firms executing outright under the US Department of Defense (DoD), its contractors who may enter into subcontracts, and firms furnishing materials and services. A good overview of the DIB sector is provided by a video and its transcript at a website containing information related to the Department of Homeland Security (DHS 2019b).

The DIB sector is quite unlike and as a matter of fact substantially different from other critical infrastructure sectors. This is mainly because the DIB is determined by the stakeholder instead of by goods and services. The sheer magnitude and multifariousness of the DIB sector ensues in new dimensions. For example, the DIB sector has an inordinately large and composite aggregation of industrial locations and manipulators. These locations and manipulators in fact span "15 subsectors and more than 90 segments governed by multiple regulations, laws, treaties, and precedents" (DHS 2019b). The 15 subsectors include industries related to shipbuilding, aircraft, missiles, space, combat vehicles, ammunition, weapons, troop support, information technology, electronics, and commodities related to industries pertaining to electronics, electrical, mechanical, and structural engineering, and also research and development facilities (DHS 2019b).

The facilities and installations that are present in the DIB sector are often dissimilar from one another. This means that uniform risk assessments are indeed not really feasible. As a result, defense-related commercial enterprises therefore place substantial focus on defending their assets and functions. As a consequence, the DIB sector has assigned priorities for partaking data and formulating appraisal and security processes that are enforced throughout the sector. Many programs have been specially designed to address various challenges that are thrown up. For example, the Defense Critical Infrastructure Program (DoD 2019) discovers, evaluates, and increases security around assets essential for executing the US National Military Strategy. Mission Assurance Assessments are also used to enforce critical infrastructure and key resource protection approaches.

Nowadays, cyber security has become a major universal problem. This has undoubtedly been hastened by the universal digitization of information. This has brought in a big risk of exposure or danger to unclassified program information controlled by the DoD. This could in turn nullify technological superiority and combat readiness and potential of the United States. Consequently, the DIB Cyber Security/Information Assurance Task Force was launched under an authorization from the Deputy Secretary of Defense. This was done to extenuate cyber risk to acquisition programs by defending Department of Defense-controlled unclassified information on corporate

networks in the unclassified sector. Additional measures have also been taken. To illustrate, the Defense Security Information Exchange, which is a sub-council of the DIB Sector Coordinating Council constitutes several defense contractors who apportion cyber threat and cautionary information. The DIB Cluster Buffer Zone Protection Program Pilot named geographical hubs where many critical assets are clustered. This program received a Buffer Zone Protection grant through the Federal Emergency Management Agency. The FY 2010 Buffer Zone Protection Program proved to be beneficial. Through the abovementioned initiatives and other measures of a similar nature, the DIB sector partners work collectively in order to preserve and raise the protective strength of the sector while safeguarding the United States.

Sector-Specific Agency

Sector-specific agencies are US government departments and authorities identified under the Homeland Security Presidential Directive 7/HSPD 7 and its successor PPD-21 for taking care of the particular critical infrastructure sector. The Department of Defense serves as the sector-specific agency for the DIB sector.

Sector Partners

According to the Department of Homeland Security (DHS 2019a), the DIB partnership consists of Department of Defense components, over one hundred thousand DIB companies, and necessarily even their subcontractors, all of them perform under contract to the Department of Defense. The partnership also includes "companies providing... [accompanying] materials and services to the Department of Defense... [in addition to] and government-owned/contractor-operated and government-owned/government-operated facilities... [and] domestic and foreign entities... with production assets ... [situated in several] countries" (DHS 2019a).

The DIB sector implements the National Infrastructure Protection Plan (NIPP) (refer DHS (2010) and DHS (2013)) by bettering industry security. This is achieved through joint activities with several security partners including defense industry associations and agencies traversing various levels of government. There are two main councils which make the task of coordination achievable and pragmatic. They are:

- Government Coordinating Council (GCC)
- Sector Coordinating Council (SCC)

Government Coordinating Council

This council ensures harmonious operations of various DIB sector security schemes, courses of action, and naturally intercommunication throughout and among the government and DIB security partners with the aim of supporting the national security goals of the United States.

Sector Coordinating Council

The DIB Sector Coordinating Council serves to network private sector owners or operators to work together with many government authorities for critical infrastructure protection. This council offers a single point of contact for interaction on a broad range of sector-specific infrastructure protection actions and matters. Many major private sector companies and associations are members of this council. The key focus areas of this council include:

- Information and Cyber Security
- Information Sharing
- Risk Management
- Personnel and Physical Security

Sector Dependencies and Interdependencies

Many of the 16 critical infrastructure sectors share common attributes with other critical infrastructure sectors. The DIB sector is therefore not an exception. This sector has many things in common with other critical infrastructure sectors, for example, with sectors such as "communications, critical manufacturing, energy, information technology, and transportation systems" (see DHS 2019b). The connections between the DIB sector

and the abovementioned sectors are briefly illustrated below:

DIB Sector and the Communications Sector

The DIB sector is obviously dependent on communications to fulfill much of its operations. For instance, two or more subcontractors of the DoD may wish to communicate and collaborate for fulfilling an upcoming highly confidential order. The Secretary of Defense may perhaps wish to accomplish national command authority functions, intelligence functions, and also share information with commanders. Hence, any major or severe breakdowns of communications could have a cumulative and deleterious effect on other critical infrastructure sectors as well. Thus, it becomes important to safeguard communication facilities against attacks; this includes attacks by physical means as well as through cyber means. The DoD accomplishes this task by protecting the United States from the harmful effects of these attacks by forewarning relevant organizations.

DIB Sector and the Critical Manufacturing Sector

The DIB sector and the critical manufacturing sector by design have a number of common features as well as interdependencies. These two sectors are primarily production sectors since they are essentially based on assets. The diverse assets make commodities that move within the sector, and mutually add to the further yield of each sector.

DIB Sector and the Energy Sector

PPD-21 named the energy sector as being singularly vital because that sector is absolutely necessary for other critical infrastructure sectors. However, regrettably, a significant proportion, in fact, more than 80% of the US energy infrastructure is controlled by the private sector. This effectively means that the US government has virtually little hold on that sector. However, the energy sector is undoubtedly cognizant of its exposures to malicious attacks and is therefore guiding a substantial conscious attempt to step-up preparation and readiness. Active help from industry has led to significant sharing of good practices throughout the sector. Numerous private energy sector proprietors and manipulators have in fact gained wide experience with infrastructure protection. Computerization and networking have brought many benefits but also significant threats to the energy sector. Thus, the focus of the energy sector has recently been on tackling threats due to deficient cyber security.

Nowadays, nuclear energy plays a significant role in the energy sector. The US Department of Energy works to increase national security through the military application of nuclear energy. It provides the US navy with dependable, militarily effective nuclear propulsion plants and guarantees their continued safe and steady-going operation.

DIB Sector and the Information Technology Sector

The DIB sector is an asset-based production sector, so it is contingent upon information that stays on and runs in a free manner among several government and often even corporate IT networks and systems. Needless to say, vital technology information, proprietary design information, information concerning military potentiality necessities, and so on must be coordinated and contemporized. Consequently, reliability, confidentiality, integrity, and availability of information are very crucial for DIB sector operations and hence their overall effectiveness.

DIB Sector and the Transportation Systems Sector

The DIB sector uses airway, seaway, railway, highway, and waterway networks to move equipage to assist the activities of the armed forces. Hence, the transportation sector is clearly very vital for the DIB sector. Thus, detrimental attacks on transportation networks through air, sea, or land must be prevented without any lapse.

Why Is the DIB Sector Vital to the United States?

As mentioned earlier, the DIB sector is one of the 16 critical infrastructure sectors. Hence, according to the Critical Infrastructures Protection Act of 2001 (GPO 2010), “the sector’s systems

and assets, whether physical or virtual, are vital to the United States. The incapacity or destruction of such systems and assets would have a debilitating impact on security, national economic security, national public health or safety, or any combination of those matters."

Plans Specific to the DIB Sector

Each of the 16 critical infrastructure sectors has a sector-specific plan that pinpoints the application of the National Infrastructure Protection Plan (NIPP) (DHS 2010) model for the specific features of that sector. Thus, in the year 2010, a plan (see DHS 2010) was prepared for the DIB sector. This plan describes how the 2009 NIPP risk management fabric is applied for the DIB sector. The DIB Sector-Specific Plan of 2010 is in fact an extension to the National Infrastructure Protection Plan of the year 2009. This particular plan provided a model for an organized national endeavor to protect critical infrastructure. It ensured the inclusion of various tiers of the government, the private sector, the academic world, and even international organizations and associates. The National Infrastructure Protection Plan of the year 2009 has been superseded by the NIPP of the year 2013 (see DHS 2013). The main goals of this revised plan include protection of critical infrastructure assets, key resources, and ensuring resiliency. Needless to say, the plan of the year 2013 attempts numerous improvements to the earlier plan of 2009. This is achieved by taking note of several changes to the risks, policies, and operating environments of critical infrastructures. The revised plan also takes care of the requisites of integrating the cyber, physical, and human elements of critical infrastructure for managing risk. Its emphasis is on collaboration for managing risk and steps to be taken for advancing the national efforts for protection of vital infrastructure.

Protective Programs and Initiatives

As mentioned earlier, in the section that provides an overview of the DIB sector, the DIB sector partners place considerable emphasis on defending their assets and functions. A cornerstone of best practices thus helps to formulate sector-wide security programs beneficial for businesses of all extents and types pertinent to the DIB sector. Some of the major initiatives within the sector are listed below:

The Defense Critical Infrastructure Program (DoD 2019a) aims to guarantee that assets, especially those that are networked and crucial to DoD military missions, are always available when needed. Actions under this program admit the recognition, judgment, and security improvement of assets indispensable for accomplishing the US National Military Strategy.

Mission Assurance Assessments garner and put through critical infrastructure protection approaches.

The Defense Industrial Base Cyber Security/Information Assurance Task Force, the Defense Security Information Exchange, and organizations such as the Critical Infrastructure Partnership Advisory Council (CIPAC) and various committees are utilized for apportioning crucial information.

The Defense Industrial Base Cluster Buffer Zone Protection Program (BZPP) archetype was enforced to apportion information related to menaces, exposures, and plans for extenuation. The BZPP named DIB geographic hubs where multiple DIB critical assets were clustered. The pilot program led to Federal Emergency Management Agency BZPP grants for enhancing the readiness potentialities of communities near high-priority crucial assets.

Incident Management in the DIB Sector

Emergency Support Functions (ESFs) (DHS 2019c) are mainly used by the US government for organizing and supplying sources of aid and/or support that may be drawn upon when needed, primarily for efficient incident management during emergencies. ESFs are essentially the aggregation of capabilities of various government organizations and if necessary some private sector organizations for multiple purposes. For example, they may be used for providing resources and support, for ensuring implementation of programs and services that are much needed for saving

lives, for protecting property and the environment, and also for reestablishing essential services and critical infrastructure. Emergency Support Functions are basically intended to help victims and communities return to normal following inevitable happenings within the nation. ESFs align classes of sources of aid and purvey important aims for their use. ESFs employ resource management constructs before, during, and after an incident. For ease of execution during emergencies, several coordinators, primary agencies, and supporting agencies have already been clearly identified for emergency support functions. In the context of the National Response Framework, which is essentially a guide to how the nation responds to all types of disasters and emergencies, the US DoD is considered to be a support agency for all emergency support functions. The National Response Framework is a part of the National Strategy for Homeland Security.

The DIB sector acts upon many ESFs during incidents in order to address the concerns of industry. Associated ESFs are also available if required. Adverse incidents impacting the DIB necessitate appropriate response and risk management. The DoD has to share incident information on risks to DIB assets through appropriate federal and commercial channels. It is important for the DoD to take efforts to restitute impaired critical DIB assets irrespective of their location.

Sector Goals and Priorities

Sector Goals

The DIB sector attempts to assure it has the power to endorse DoD missions and do away with undesirable risk to national security. In order to attain this, the DIB sector partners have established five strategic goals (DHS 2019b):

- Employ an all-hazards mechanism to deal with risks related to reliance on critical sector assets.
- Ameliorate coaction in the circumstance of statutory, regulatory, proprietary, and other pertinent information-sharing constraints and guidance.
- Extenuate risk created by personnel with unaccompanied physical or logical access to critical sector assets.
- Handle risk created by menaces to and exposures of critical sector physical assets.
- Take care of risk to information that identifies or describes characteristics or capabilities of a critical DIB asset or by the nature of the information would represent a high risk/high impact to the critical infrastructure or the DIB asset.

Sector Priorities

The DIB sector is to a significant extent made up of privately owned and controlled businesses. As mentioned earlier, there is no sector-wide requirement for standardized risk assessments, although the DIB sector is subject to a variety of risk assessments in the areas of business operations, information security, and information assurance. It is indeed vital for all DIB businesses to invest in high-tech security and programs, notwithstanding the fact that they are often complicated in structure and to a great extent constantly high priced.

The DIB sector has assigned priorities to requirements to jointly apportion information and formulate appraisal and security processes that may be carried out throughout the sector. Toward that goal, the sector is progressing as indicated below (DHS 2019b):

- Moving aggressively to adapt longstanding stakeholder–vendor relationships to support the NIPP partnership model
- Conducting critical infrastructure assessment of sector assets, systems, networks, and functions
- Building a foundation of frequent communications between sector partners and the government

Sector-Specific Resources

Legislation

The Critical Infrastructure Information Act of 2002 (CII Act) (DHS 2019d) seeks to help better sharing of critical infrastructure information among the proprietors and operators of the critical infrastructures and also the government entities

with infrastructure protection obligations. This helps reduce United States vulnerability to terrorism. The Act (DHS 2019d) "consists of a group of provisions that address the circumstances under which the Department of Homeland Security may obtain, use, and disclose critical infrastructure information as part of a critical infrastructure protection program." The US Congress has set standards for defending critical infrastructure information by means of the CII Act of 2002. In response, the Department of Homeland Security produced the Protected Critical Infrastructure Information program (CISA 2019). The aim of this program is to guard crucial substructure information freely portioned out with the government for US national security aims. The program is also a fundamental part of efforts undertaken to defend the United States critical infrastructure from cyber-attacks.

Directives

Several directives relate to the DIB sector. A case in point is the Department of Defense Directive 3020.40 (DHS 2019d) "updates policy, and assigns responsibilities for the Defense Critical Infrastructure Program." In addition, the Homeland Security Presidential Directive 7/HSPD 7 and its successor PPD-21 laid down a national policy for government departments and agencies to distinguish and assign a priority to US critical infrastructure and key resources and to defend them from extremist attacks. Additional relevant directives include the (DHS 2019d):

- DoD Directive 5000.1 ("The Defense Acquisition System")
- DoD Instruction 5000.2 ("Operation of the Defense Acquisition System")
- DoD Directive 5000.60 ("Defense Industrial Capabilities Assessments")

Training

Many DoD agencies, academies, and organizations provide training, security education, and the ability to respond to disasters as well as emergency situations. The training is available for first responders and others. The training also provides formal instruction and counseling in assessing, identifying, and prioritizing homeland security measures.

Publications

Several publications related to the DIB sector are available (DHS 2019b). An example of such a publication is the DoD's DIB Defense Sector Assurance Plan, which furnishes a well-organized scheme for dealing with risk to industrial potentialities at critical asset locations situated all over the world. DoD has also published its "Defense Critical Infrastructure Program Infrastructure Resilience Guide," which serves as an aid to people who review infrastructure dependencies and develop and implement mitigation measures. Moreover, the Government Accountability Office published a manual, titled "Defense Infrastructure: Management Actions Needed to Ensure Effectiveness of DoD's Risk Management Approach for the Defense Industrial Base," which identified and evaluated DoD's "risk management approach to ensur[ing] the availability of DIB assets, and... identified challenges the DoD faces in its approach to risk management" (GAO 2017). Furthermore, the National Defense Industrial Association provides links to related studies, reports, and proceedings, and publishes the National Defense magazine.

Executive Order 13806

Successive US Presidents have been very keen in strengthening the manufacturing and DIB as well as the supply chain resiliency of the United States. As mentioned before, former US President Barack Obama issued the Presidential Policy Directive PPD-21 (PPD-21 2013) in Feb 2013, the subject of which was critical infrastructure security and resilience. In the year 2017, in the month of July, US President Donald Trump brought out Executive Order 13806 (White House 2017). This order was for evaluating and toughening the manufacturing and DIB and supply chain resilience of the United States.

In order to comprehend some of the issues currently faced by the DIB sector, it is instructive to study Executive Order 13806. This order mentions that the fabricating capability and DIB of

the United States have been diminished by the deprivation of over sixty thousand factories and almost five million fabrication jobs since the year 2000. It also remarks that workforce skills are important to national defense. The executive order emphasizes the need for producing "education and workforce development programs and policies that support job growth in manufacturing and the" DIB (White House 2017). The order further called for an evaluation of the DIB and supply chains, with comments from multiple administrative departments and agencies in order to allow for an absolutely needed and indispensable assessment of the current strengths and weaknesses. The assessment as requested by the executive order was published in September 2018 (DoD 2018).

The Assessment Report Produced in Response to Executive Order 13806

An interagency task force submitted an unclassified publicly accessible report (DoD 2018) in September 2018 to US President Donald Trump in fulfillment of the Executive Order 13806 of July 2017. The report which is very informative has the following major findings (DoD 2018):

- Macro forces have contributed to substantial consequences chiefly in the sublevels of the defense supply chain.
- An amazing level of dependence on rival countries subsists.
- Employers across all sectors face manpower challenges.
- A large number of sectors are actively shifting critical potentialities abroad in quest of more lucrative pricing and also for entry into foreign markets.

The assessment report begins with an overview of America's manufacturing and DIB. It then lists five macro forces forcing risk into America's industrial base (DoD 2018):

(i) Sequestration and doubtfulness of US government expenditure
(ii) Reduction of US manufacturing capability and capacity
(iii) Detrimental US government business and procurement activities
(iv) Industrial action plans of rival nations
(v) Declining US Science, Technology, Engineering, and Math (STEM) and trade capabilities

Table 1 elucidates these forces (see Fig. 7 of the report):

Ten risk archetypes threatening America's manufacturing and DIB are then mentioned in the report. Table 2 (see Fig. 23 of the report) illustrates them:

The impacts of these risk archetypes on America's industrial base are noted. These include:

- Scaled down investment in new capital as well as research and development
- Consequent decreases in the rates of modernization and technical creation
- A deprivation of providers and possible chokepoints throughout the numerous tiers of the supply chain
- More depleted quality and above normal prices ensuing from trimmed down competition

An important point to note is that the impacts identified in the assessment report (DoD 2018) often fell into multiple risk archetypes. For example, "a financially distressed foundry may be both a sole source and single source, as well as illustrate a fragile market" (DoD 2018). The assessment report gives a summary of demonstrative examples in each of the risk archetypes. A broad list of about 300 impacts for all the 16 critical infrastructure sectors was made available in a classified appendix to the report.

A Blueprint for Action

The assessment report (DoD 2018) produced in response to Executive Order 13806 (White House 2017) includes a blueprint for action. The blueprint makes a note of current efforts and lists

Critical Infrastructure: Defense Industrial Base Sector, Table 1 Macro forces

Macro forces	Explanation
Sequestration and uncertainty of US government spending	Discrepant appropriations, doubts about succeeding national budgets, macrolevel equivocalness in US government outlays, and the consequences of the budget control act make markets precarious
Decline of US manufacturing base capabilities and capacity	Diminutions throughout the fabricating and defense industrial base of the United States impact the usefulness of providers, overall capability, and capabilities operational across the country
Deleterious US government business and procurement practices	Demanding situations when dealing with the DoD and other US government clients, including contractual arrangements, ordinances, policies, roadblocks to involvement, qualification disputes, alterations of plans, and other troubles can contribute to untoward impressions on providers
Industrial policies of competitor nations	The national industrial policies and the external trade policies of rival nations, particularly the economic aggressiveness of China, bring down the usefulness, capabilities, and capacity of the US National Security Innovation Base
Diminishing US STEM and trade skills	Disruptions in US human capital, in particular a deficiency of STEM natural endowments and worsening trade skills decrease national capacity to develop something new, fabricate, and uphold

Source: Fig. 7 of DoD (2018).

Critical Infrastructure: Defense Industrial Base Sector, Table 2 Risk archetypes threatening America's manufacturing and DIB

Risk archetype	Occurs when
Sole source	Just one supplier is in a position to furnish the needed capability
Single source	Just one supplier has measured up to stipulated norms to furnish the needed capability
Fragile supplier	A particular supplier is in a state of woe from a financial point of view
Fragile market	The economics of an industry are not robust and the possibility of nearing liquidation is imminent
Capacity-constrained supply market	Capacity is out of stock in wanted amounts or time due to vying market requirements
Foreign dependency	The national industry does not make the product or does not make it in ample amounts. Hence, there is dependence on foreign sources
Diminishing manufacturing sources and material shortages	Product or material devolution ensuing from slump in germane providers
Gap in US-based human capital	The industries in the United States are not in a position to employ or retain workers with the desired skill sets due to manpower shortages
Erosion of US-based infrastructure	Expiration or obsoleteness of specified capital equipment required to incorporate, fabricate, or preserve capability
Product security	Deficiency of cyber and physical safety ensues in degradation of unity, assurance, and competitive benefits

Source: Fig. 23 of DoD (2018).

future efforts and recommendations. The recommendations include (DoD 2018):

- Creating an industrial plan of action endorsing national security efforts
- Amplifying direct investment in the bottom levels of the industrial base and programs to deal with decisive chokepoints, patronize delicate suppliers and extenuate single points-of-failure

- Branching out from everlasting reliance on sources of supply in politically fluid countries who may interrupt access by the United States
- Working together with friendly nations and collaborators on articulated industrial base challenges
- Modernizing the organic industrial base
- Accelerating workforce development efforts
- Reducing the personnel security clearance backlog
- Enhancing efforts exploring next generation technology for future threats

Conclusion

The defense industrial base sector is a critical infrastructure sector which needs to be fortified and preserved. The differences between the DIB sector and other sectors arise because the DIB is defined by the stakeholder. The DIB sector has an incredibly large number of partners which adds to its complexity. It has many dependencies and interdependencies with other critical infrastructure sectors. The DIB sector is very vital to the United States and many sector-specific plans have evolved and continue to evolve. A number of initiatives and protective programs have been launched to safeguard the DIB sector. Executive Order 13806 has had a major effect in revitalizing the DIB sector. Numerous challenges need to be addressed and these can be handled if appropriate measures are taken right away as suggested by the assessment report produced in response to the order.

Critical Infrastructure: Emergency Services Sector

Brian Keith Simpkins
Homeland Security Program, Eastern Kentucky University, Richmond, KY, USA

Keywords
Dependencies · First Responder · Interdependencies · Natural Hazards · Risk Profile

Definition

Critical Infrastructure	"Systems and assets, whether physical or virtual, so vital to the United States that the incapacity or destruction of such systems and assets would have a debilitating impact on security, national economic security, national public health or safety, or any combination of those matters" (Uniting and Strengthening America by Providing Appropriate Tools Required to Intercept and Obstruct Terrorism [USA PATRIOT] Act 2001).
Emergency Services Sector	The Emergency Services Sector (ESS) provides services to all five mission areas defined in the National Preparedness Goal: prevention, protection, mitigation, response, and recovery (U.S. Department of Homeland Security [DHS] 2015c). The services are provided by career and volunteer first responders and associated capabilities and resources across the county at the federal, state, and local levels as well as the private sector (U.S. Department of Homeland Security [DHS] 2015a).

Introduction

Each and every day, the Emergency Services Sector (ESS) plays an important role in safeguarding lives and property across the United States. Although the ESS responds when assets in other critical infrastructure sectors need assistance, the sector itself faces challenges to security and resilience. Some of the risks faced by the ESS are similar to other infrastructure sectors, such as a changing threat and hazard picture, climate change, and cyber-attacks through increased reliance on Internet-connected systems. These high-level challenges are just the beginning as the ESS faces a myriad of other risks related to natural hazards, technological hazards, and human-caused incidents. This is in addition to dependencies and interdependencies with other infrastructure sectors, which can result in significant cascading effects.

The remainder of this entry provides a general overview of the ESS to enable a general understanding. Within the discussion, key operational characteristics of the ESS are reviewed along with a description of the current risk profile to include critical cross-sector dependencies and interdependencies. This discussion will also include vision/mission, goals, and priorities of the ESS along with the partnership structure. Partnerships and

information sharing within the ESS have extreme importance in order to address and respond to human-caused incidents that can result in significant casualties and damage to infrastructure assets. Overall, this entry provides a basic understanding of the ESS to enable critical evaluation of current policies, practices, and needed activities to address gaps in security and resilience.

Sector Overview

The ESS has the primary protection responsibility of other critical infrastructure sectors and assets. The ESS is the first line of defense for all mission areas (prevention, protection, response, recovery, and mitigation) related to natural hazards, technological hazards, and human-caused incidents that may affect infrastructure assets. To accomplish this task, the ESS consists of millions of highly skilled first responders (human element) along with physical and cyber assets/elements. Consisting of both paid and volunteer forces, the ESS is organized/structured at the federal, state, local, tribal, and territorial levels of government. Therefore, ESS agencies include the primary public first responder agencies at each government level. ESS assets also include personnel and associated resources within the private sector such as private security and fire/emergency medical services at industrial sites. Due to the focus on the protection of other infrastructure sectors and assets, the ESS faces distinctive challenges in security and resilience of ESS assets, such as communications and data networks. The disruption of physical or virtual ESS assets can result in significant consequences to public safety and security.

Sector Components and Assets

The ESS has components related to the human, physical, and cyber elements. For human, the ESS is comprised of paid and volunteer individuals within the primary response disciplines. For physical, this realm includes ESS facilities from which daily operations are administered as well as facilities that support training and storage. Additional physical assets include equipment (e.g., personal protective [PPE], communications, and surveillance equipment) and vehicles (e.g., ambulances, patrol vehicles, fire apparatus, aircraft, and watercraft) that are specialized for specific disciplines and for capability. In regard to cyber, this element includes operational communications (e.g., two-way radio systems), databases (e.g., criminal record databases), management (e.g., incident decision support software), biometric systems, security systems, and information networks (e.g., computer-aided dispatch [CAD]). Aside from human, physical, and cyber realm, the ESS is officially compartmentalized into five distinct emergency responder disciplines or subsectors as described below per the *Emergency Services Sector-Specific Plan* (ES SSP).

Law Enforcement: Consists of police departments, sheriff's offices, courts systems, correctional institutions, and private security agencies. Provides services such as enforcing laws, conducting criminal investigations, collecting evidence, apprehending suspects, securing the judicial system, and ensuring custody and rehabilitation of offenders.

Fire and Rescue Services: Consists of both paid and volunteer personnel. Provides services such as fire suppression, fire prevention, hazardous materials control, life and property safety operations (including technical rescue), building code enforcement, and fire safety education.

Emergency Medical Services: Provides services at incidents such as triage, treatment, and transport of injured and ill patients; taking appropriate steps to protect staff, patients, facilities, and the environment; and helping to monitor response teams while providing needed comprehensive medical care to patients.

Emergency Management: Provides incident management and coordination (including pre- and postevent activities) between ESS disciplines, as well as with nonemergency services entities. Emergency Operations Centers (EOCs) provide emergency management personnel with the capability for multiagency coordination for incident management by activating and operating for preplanned or

no-notice events. EOCs support the coordination of response and recovery activities among neighboring jurisdictions at and all levels of government if needed.

Public Works: Provides service such as assessing and repairing damage to buildings, roads, and bridges; clearing, removing, and disposing of debris from public spaces; restoring utility services; and managing emergency traffic. With responsibility for hardening security enhancements to critical facilities and monitoring the safety of public water supplies, public works is an integral component of a jurisdiction's emergency planning efforts. In addition, public works departments supply heavy machinery, raw materials, and emergency operators and may also manage contracts for additional labor, equipment, or services that may be needed before, during, and after an incident (U.S. Department of Homeland Security [DHS] 2015a, p. 5).

In addition to the responder disciplines/subsectors, the ESS also consists of specialized personnel and teams that provide additional emergency response capability when appropriate. This specialized capability can be present in one or more of the responder disciplines/subsectors and can focus in areas such as special weapons and tactics, hazardous materials, explosive ordinance disposal, search and rescues (air, land, marine), and National Guard Civil Support (DHS 2015a).

Key Sector Operating Characteristics

As previously stated, the ESS has the primary protection responsibility of other critical infrastructure sectors and assets and acts as the first line of defense in relation to natural hazards, technological hazards, and human-caused incidents that may affect infrastructure assets. This responsibility is handled by more than 2.5 million first responders that serve in all 56 US states and territories (DHS 2015a). Decisions made by the ESS in response to incidents can affect the level of damage inflicted to infrastructure and how quickly services are restored. Although the ESS operations are required to be adaptable and flexible to address any incident, the sector does have limitations when facing incidents and disasters – or circumstances – which have not been training for or previously experienced. Overall, the graphically dispersed aspect of the ESS makes it difficult to completely disable nationwide, but this aspect also creates challenges in across government levels and responder disciplines. Further, the ESS is driven by the human element, but is dependent on the cyber element (e.g., communications, information technology) and physical element (e.g., response vehicles and equipment).

Another limitation of the ESS is limited resources, especially in ESS agencies located in small and rural communities. Not only have operational budgets within local and state ESS agencies decreased over the past decade, but federal grant funding for ESS agencies has also vastly decreased over the same time period. Limited financial budgets affect the operational capacity of ESS agencies (e.g., less personnel, use of older/outdated equipment) to address and respond to current risks and adapt to changing risks. Resource constraints are just one operational consideration of the ESS, and others include the following:

Rural and Frontier Resource Constraints: In rural and frontier communities, limited populations and smaller tax bases create difficulties and shortcomings for ESS agencies in terms of staffing, equipment, and other resources.

Geography: The ESS operates in density-populated urban environments as well as in vast and, oftentimes, sparsely populated areas, both of which provide significant challenges. For example, in rural and frontier areas, greater distances traveled and difficult on-road and off-road terrain (e.g., mountains, marshlands, wilderness) may significantly impact response planning and operations.

Infrastructure: Although urban ESS agencies may benefit operationally from an increased presence of infrastructure, it also creates more infrastructure to protect. As for rural areas, many segments of critical infrastructure, such as hospitals and other healthcare facilities, are less capable (e.g., have fewer physicians and

specialists per capita) than similar infrastructure in urban areas for various reasons. These conditions may limit response to public health hazards such as communicable diseases.

Modernization: Citizens of all communities continue to demand that ESS agencies modernize systems despite resource shortages. Today, approximately 88% of US adults own a cell phone and 78% access the Internet. ESS agencies must upgrade their own equipment as well as 9-1-1 centers, warning systems, and online resources for the benefit of their residents (Simpkins 2015, p. 3).

All of the constraints above are intensified by the fact that a majority of ESS personnel are volunteers. For example, volunteers are often assigned as county emergency managers and/or required to fully staff rural fire departments (U.S. Fire Administration 2007). This occurrence does not happen in rare circumstances. Rather, rural areas constitute 80% of the landmass and 20% of the population in the United States (McGinnis 2004). Additionally, frontier areas are classified as areas with an extremely low population density (less than six persons per square mile) and are characterized by isolation from population centers (e.g., cities) and provision of services (e.g., hospital, cell phone service), which comprise approximately 2% of the US population and 46.7% of the land within the Unites States (largely concentrated in the Western United States and Alaska) (National Center for Frontier Communities 2013).

Across the United States, ESS missions are completed by approximately 2.6 million individuals in the law enforcement, fire and rescue, emergency medical services (EMS), emergency management, and public works disciplines (DHS 2015a). This is in addition to ESS personnel within the private sector that includes industrial fire departments, corporate security operations, and private EMS providers. As for the number of rural first responders, there is no single source for a specific number. However, descriptive information can be gleaned from various sources. For example, the National Institute of Justice (2004) reports that approximately 90% (or ~14,500) of the over 16,000 municipal and county law enforcement agencies in the United States serve populations under 25,000 and over half of all agencies employ 10 or fewer officers. Further, the US Fire Administration (2007) reports that 44% (or ~13,440) of the over 30,000 fire departments in the United States are located in rural areas.

Similar to other critical infrastructure sectors, the ESS is not heavily regulated, but specific regulations govern or provide reference for use in emergency response operations (e.g., hazardous materials incidents), responder safety (through the Occupational Safety and Health Administration [OSHA], and professional codes and standards for fire prevention and public safety (through the National Fire Prevention Association [NFPA]). Despite limited regulation, the agencies across the ESS rely heavily on communications and information technology networks during incident response. Protecting these networks is essential for ESS agencies to support critical infrastructure security and resilience as well as to ensure the provision or quick restoration of essential public services and infrastructure assets.

Sector-Specific Agency

The US government by itself cannot create a secure and resilient ESS. Rather, the end goal requires a dedicated whole-of-nation approach involving public and private stakeholders. Leading this whole-of-nation approach is the designated Sector-Specific Agency (SSA) as defined in *Presidential Policy Directive (PPD) 21: Critical Infrastructure Security and Resilience*. The designated SSA for the ESS is DHS. More specifically, the Office of Infrastructure Protection is the delegated responsible entity within DHS.

Sector Partnerships

Security and resilience of the ESS requires a broad spectrum of partnerships to facilitate information sharing and situational awareness to address sector risks. Specific partnership structures are defined within the ES SSP. However, the ESS utilizes the *National Infrastructure Protection Plan* (NIPP) partnership structure and additional collaboration mechanisms based on Government

Coordinating Councils (GCC) and the Sector Coordinating Councils (SCC). Beginning with the SCCs, these councils are comprised of owners and operators who utilize the council to directly collaborate with one another. Typically organized under subsectors within an overall infrastructure sector, SCCs are self-organized, self-run, and self-governed councils and serve as principal collaboration points between the GCCs and the SSAs. Conversely, the GCC focuses on collaboration and information sharing between the SSA, or federal departments and agencies, and state, local, tribal, and territory (SLTT) agencies. Members of the GCC and the SCC utilize collaborative mechanisms, such as the Critical Infrastructure Partnership Advisory Council (CIPAC) to facilitate collaboration and information sharing across the public and private sectors. These collaborative partnerships and subsequent information sharing are crucial to achieving infrastructure security and resilience. This enables public and private entities to freely share information to identify mutual risks and potential solutions that benefit entire sectors. Through the defined partnership structures of the ESS, overall security and resilience posture of the sector can be continuously improved.

Sector Risks

Despite the diverse collection of assets within the ESS, common risks exist that the sector must address. Climate change, extreme weather, terrorism, and malicious actors are persistent risks across the ESS (DHS 2014). Further, cyber vulnerabilities continue to increase as reliance on networked systems continues to rise in an effort to increase efficiency and cost-effectiveness. Some of these threats are more pronounced in the ESS due to the need for open public access and the responsibility to respond to any incident. This illustrates the need to comprehensively examine risks across the ESS through existing partnership structures in an effort to ensure security and resilience. Although numerous risks can be discussed, the following sections focus on those risks deemed significant. It is acknowledged there are other significant risks to the ESS, such as the loss of two-way communications. However, these risks will not be discussed for the sake of brevity. Expanded information on risks to the ESS is accessible via the ES SSP.

Cyber Risks

The cyber threat is common throughout all critical infrastructure sectors including the ESS. Information networks and other technology resources are vulnerable to various types of attacks, which continue to increase in occurrence and severity thereby resulting in significant risk to the ESS (DHS 2012, 2015b; U.S. Government Accountability Office [GAO] 2008, 2014; Green 2016). In fact, the cyber threat is considered one of the most serious threats to all critical infrastructure sectors. Like other infrastructure sectors, the ESS is heavily dependent on cyber infrastructure and operates in a data-driven environment. Further, much of the cyber infrastructure utilizes commercial-off-the-shelf (COTS) products and systems, which have inherent vulnerabilities to malicious individuals. Individuals both inside and outside of the United States attempt to exploit the vulnerabilities, which puts current and future ESS capabilities at risk. In fact, the US Department of Defense (2011) *Strategy for Operating in Cyberspace* predicts the risk from foreign entities and non-state actors attempting to exploit cyber vulnerabilities will continue to increase in the future.

Ultimately, cyber vulnerability also poses a significant threat to the ESS sector and its ability to fight crime and complete other essential missions related to public safety and security. Most importantly is the ability to communicate, including the ability for citizens to reach ESS agencies via 9-1-1 services. More than just call centers, public-safety answering points (PSAPs) utilize information technology systems that merge phone numbers with geographic and other location data. These systems are vulnerable due to the increasing reliance on the Internet for operations, which makes 9-1-1 services susceptible to cyber-attacks. It is expected that attacks on ESS communication networks will become more frequent in the future (DHS 2015b; Green 2016). Between 2013 and 2016, over 600 critical

government phone systems and 200 PSAPs nationwide were affected by telephony denial of service attacks (Green 2016). In addition to communications, the ESS is increasingly reliant on other cyber-based infrastructure for data and information management (including cloud-based systems), biometric activities, electronic security systems, and geospatial tools. Due to this connectivity, ESS cyber infrastructure is vulnerable to cyber-attacks (e.g., denial-of-service attacks, phishing, passive wiretapping, Trojan horses, viruses, worms) from individuals and group operating around the world (DHS 2015b; GAO 2014; Green 2016).

Another common threat to all computers and networks is ransomware, which encrypts or otherwise disables access to information unless a ransom is paid (a common form of payment requested is Bitcoin). The ESS is vulnerable to this threat as illustrated by multiple ESS agencies being targets of ransomware attacks since 2014 in states such as California, Nevada, Wisconsin, and North Carolina. These attacks can disrupt initial response by ESS agencies to an incident as well as endanger first responders and members of the general public. Ultimately, the ESS is increasingly dependent upon information technology networks for multiple operations, which greatly amplifies vulnerability to cyber-related incidents.

Climate Change, Natural Hazards, and Extreme Weather

As with other infrastructure sectors, the ESS is impacted by climate change. Not only are climate change risks present; their rate of occurrence and level of severity are increasing including their effects on natural hazards. Regardless of the natural hazard/disaster or extreme weather event, the ESS is faced with sometimes unpredictable natural threats in a dynamic response environment. Increased occurrence and severity of natural hazards place increased demands on ESS assets and threaten the provision of key services. These events are increasing in terms of geographic magnitude and severity thereby requiring a surge of ESS assets for extended operational periods. A recent example is the catastrophic flooding in the Houston (TX) due to Hurricane Harvey in late August 2017. In addition to ESS response personnel, natural hazards can also impact cyber infrastructure. This impact can be significant as 9-1-1 communication networks can be disrupted. Further, impacts from natural hazards can also impact ESS operational communications networks, such as two-ways radio communications.

Two events illustrate the risk from natural hazards to 9-1-1 communication systems and operational communications networks. First, a major storm during June 2012 resulted in a total disruption of telephone services supporting 9-1-1 service across several cities and counties in Virginia (GAO 2014). The service outage was a result of loss of main commercial power and subsequent failure of a backup generator in the telephone service provider's facilities (GAO 2014). The lack of redundant measures and mitigation planning contributed to a significant disruption of public service answering points (PSAP) operations during the outage (GAO 2014). Second, Hurricane Katrina resulted in the destruction or degradation of three million landlines, 2,000 cell towers, more than 30 public service answering points (PSAPs), 37 of 41 broadcast radio stations, and first responder land mobile radio service across the region (Miller 2006; Select Bipartisan Committee to Investigate the Preparation for and Response to Hurricane Katrina 2006). Satellite phones were in short supply and unable to be charged due to lack of electrical power and fuel to run emergency generators (Miller 2006; Select Bipartisan Committee to Investigate the Preparation for and Response to Hurricane Katrina 2006). The New Orleans (LA) Police Department and the Mississippi National Guard were unable to establish effective communications for several days (Miller 2006; Select Bipartisan Committee to Investigate the Preparation for and Response to Hurricane Katrina 2006). In addition to operable communication, situational awareness was nonexistent due to a lack of interoperability between federal, state, and local communications systems (Miller 2006; Select Bipartisan Committee to Investigate the Preparation for and Response to Hurricane Katrina 2006). This illustrates that the continued increase in the occurrence and severity of natural hazards

will place demands on the ESS to mitigate operational disruptions while addressing increased public demand for service.

Epidemics and Pandemics

Evolving threats to the ESS include infectious disease occurrences, which can include diseases such as Ebola, smallpox, tuberculosis, severe acute respiratory syndrome (SARS), and Middle East respiratory syndrome (MERS) (National Infrastructure Advisory Council 2007). Infectious diseases can spread easily in today's highly mobile society and can easily morph into an epidemic (affecting a localized area) or pandemic (affecting a large region) (National Infrastructure Advisory Council 2007). A critical impact of an epidemic or pandemic is the loss of ESS personnel due to infections. Therefore, emerging and re-emerging infectious diseases must be planned for as ESS personnel would be important response assets. However, variation is persistent across the nation in terms of community fiscal health, at-risk population levels, training competencies, and countermeasure availability when addressing infectious disease epidemics and pandemics. These events can also have significant, long-term impacts on communities, especially in relation to high-risk and vulnerable populations. In fact, the United States has a constant risk of an onset of a severe influenza pandemic, and the influenza season of 2014 provides insight into the risk and how a rapidly spreading infectious disease can impact the ESS. A more concerning thought, however, is the intentional release of a more dangerous infectious disease such as smallpox and the catastrophic impacts on the nation if its spread is not readily contained.

Terrorism, Violent Extremism, and Malicious Actors

Due to the nature of their work, ESS personnel are vulnerable to human-caused incidents to include terrorism and actions by malicious actors to include active shooters. This is especially true for the ESS which perpetually faces the challenge to prepare for current threats as well as evolving threats that may require new or expanded capabilities and competencies. Further, response personnel can become targets of (secondary) attacks when responding to human-caused events in which an attacker's goal is to achieve a maximum amount of casualties. This is especially true if adversaries are targeting persons in specific authority positions or are symbolic of a social institution. Adversaries can include terrorists and violent extremists, who often target ESS personnel and symbolic targets.

Improvised Explosive Devices

The use of improvised explosive devices (IEDs) continues to be a common asymmetrical attack method by terrorists and violent extremists. Not only can IEDs damage infrastructure and cause mass causalities; they can also be used to target ESS personnel when responding to an initial incident through secondary devices. Another common practice is the simultaneous use of IEDs at multiple locations, which is specifically designed to affect ESS agency response efforts. Further, active shooter events can incorporate IEDs in an effort to increase causalities or hamper and slow down response from ESS agencies. For example, the perpetrators of the San Bernardino (CA) shooting on December 2, 2015 placed a pipe bomb in the Inland Regional Center, but was not detonated (Winton and Queally 2016). Overall, the threat of IEDs is constant across many infrastructure sectors, including the ESS.

Primary Sector Dependencies and Interdependencies

Today, critical infrastructure sectors are highly dependent and interdependent on one another through physical and cyber linkages. After a natural disaster, man-made incident, or technological accident, a significant failure in one sector – such as in the Energy Sector or Water and Wastewater Systems Sector – has the potential to cascade and create significant impacts to other regions. Currently, the ESS has dependencies on the sectors of Communications and Information Technology and interdependencies with the sectors of Energy, Transportation Systems, Water and Wastewater, Government Facilities, and Healthcare and Public Health (DHS 2014, 2015a). Descriptions of select

dependencies and interdependencies are provided below.

Communications: Provide essential services to ESS for daily operations and other activities. Of particular importance is ESS response coordination communications and public alert and warning.

Energy: Fuel and electric power are essential for operations within the ESS. This includes ESS response activities and daily business operations, movement of resources, and response coordination.

Information Technology: Provides essential services to the ESS in support of a variety of cyber-related assets and essential to operations and fulfillment of mission responsibilities. With increasing dependency on cyber-related assets and systems, disruptions or degradation of service would significantly impact the ESS, including the capability to adequately protect the public and safely and quickly respond to emergencies.

Transportation Systems: Secure and effective movement of personnel, resources, and services over multiple modes is required for the ESS. Specifically, response vehicles must be able to transport people, resources, and services to and from incident areas.

Water and Wastewater Systems: Critical for sustaining communities and infrastructure before, during, and after emergencies and is a basic human need vital to human health. For example, the ESS relies on water in response to fires and natural disasters (e.g., bottle water distribution) (DHS 2014, p. 20; 2015a, p. 4, 9–10).

In addition to external dependencies and interdependencies between sectors, the ESS also experiences internal interdependencies similar to other sectors. This is because each responder discipline within the ESS is interdependent on one another for continued functioning. For example, law enforcement secures emergency scenes for fire services and EMS to provide needed services. Additionally, public works ensures roadways are clear of debris to facilitate emergency scene access for other response disciplines. Today, the continual operation of the ESS is dependent and interdependent on other infrastructure sectors. Greater dependences and interdependencies, especially in the cyber realm related to communications and information technology, create the potential that even a localized disruption will have the ability to cascade to other sectors. This is in addition to vulnerabilities within the global and national supply chains that can pose significant disruptions to public safety and security.

Sector Vision, Goals, and Priorities

In alignment with the NIPP, each SSA develops a specific vision and/or mission for their respective infrastructure sector, which is defined in individual SSPs. Listed below are the specific vision and vision statements for the ESS.

Vision Statement: An Emergency Services Sector in which personnel and operational capabilities are prepared for and resilient to inherent and unforeseen risks; ensuring timely, coordinated all-hazards emergency response and public confidence in the sector.

Mission Statement: Save lives, protect property and the environment, assist communities impacted by disasters, and aid recovery during emergencies (DHS 2015a, p. 26).

In addition to defining the vision and/or mission, the ES SSP identifies specific goals and priorities aligned with the five overall national goals defined in the NIPP, which are provided below.

Sector Goals

1. Continuous growth and improvement of sector partnerships to address risk mitigation and resilience efforts (*NIPP Goal #4*).
2. Support an information sharing environment for information, intelligence, and incident reporting (*NIPP Goals #4 and #5*).
3. Employ a risk-based approach to improve the preparedness and resilience (*NIPP Goal #1*).
4. Improve operational sustainability, resilience, and recovery capacities following an incident (*NIPP Goals #2 and #3*) (DHS 2015a, p. 27).

Sector Priorities

1. Utilize collaborative approaches to strengthen critical infrastructure protective planning and decision-making.
2. Develop and promote information sharing via councils and new, innovative processes and technologies to support protective programs; share risk, capacity building, and model practices information; and improve resource sharing systems and standards.
3. Identify and implement an approach/process to assess and prioritize risk and capability gaps in the ESS to enhance the resilience and recovery capabilities following an incident.
4. Develop and report metrics to measure effectiveness of efforts and gather a means to measure effectiveness (DHS 2015a, p. 27).

Conclusion

The ESS encompasses critical missions that if significantly disrupted or degraded would result in disastrous consequences to the safety and security of US citizens, protection of critical infrastructure, and overall public safety and security. For example, successful intentional cyber or physical attacks on ESS assets could impact domestic emergency response and the provision services to individuals in need. This is in addition to the ever-present risks from natural hazards, which is increasing due to climate change. Therefore, the risk profile of the ESS continues to evolve. These risks include actions happening on the world stage as well as actions within numerous dependent and interdependent infrastructure sectors. Per the NIPP, risks must be continuously evaluated and addressed, especially in the ESS due to its role in US domestic security.

Definition

Security for the Government Facilities Sector (GFS) involves protection of business, judicial, educational, and cultural activities in governmental facilities (Office of Infrastructure Protection 2015).

Introduction

The GFS encompasses federal government facilities that are owned, leased, and operated by the U S government nationally and internationally. Specifically, two US federal organizations – Federal Protective Service (FPS) of the US Department of Homeland Security (DHS) and the General Services Administration (GSA) – oversee its operation (Office of Infrastructure Protection 2015, p. 10). The GFS has two major sub-sectors, including educational facilities (EF) and the national monuments and icons (NMI) (Office of Infrastructure Protection 2015, p. 10). The Department of Education (ED) released the Education Facilities Subsector Snapshot (EDSS) outlining this subsector in 2011, based on Homeland Security Presidential Directive 7 (The White House Office of the Press Secretary 2003). At that time, there were of 18 critical infrastructure sectors (The White House Office of the Press Secretary 2003a). A full description of the 18 critical infrastructure sectors is available on the DHS critical infrastructure resource

center website. Currently, there are 16 critical infrastructures (see all of the Critical Infrastructure entries in this encyclopedia).

The GFS also has five minor sub-sectors: Federal offices and office building complexes; courthouses; archives and libraries; storage and preservation facilities; and embassies, consulates, and border facilities (Office of Infrastructure Protection 2007a, p. 1). The US Marshal Service oversees the federal courthouses. The state, local, territorial, and tribal (SLTT) governments provide protective oversight for nonfederal courthouses. The National Archives and Records (NARA), the Department of Defense (DoD), the Nuclear Regulatory Commission (NRC), and the US Mint which provides specialized oversight to the storage and preservation facilities based on the type of material stored or preserved. And finally, the US Department of State (DOS) and the customs and border patrol of DHS protect embassies, consulates, and border facilities protective measures. Information regarding the minor support agency responsibilities is available on the Homeland Security Digital Library.org website. This entry will describe the GFS sector's vision and goals, assets, and sub-sectors.

GFS Sector Vision and Goals

Chapter three of the 2015 GFS SSP outlines the sector's vision, mission, goals, and priorities (Office of Infrastructure Protection 2015). The SSP vision statement provides a balanced management of sector risks. This risk protocol would allow the government functions to operate without disruption (Office of Infrastructure Protection 2015, Chapter 3, p. 14). The necessary process used to assess risk in the GFS SSP 2015 is important because the 2015 GFS SSP mission is to reduce vulnerabilities while facilitating the resilience and continuity of our nation's operations (Cybersecurity & Infrastructure Security Agency/CISA 2013, p. 14).

In the 2015 GFS SSP, there are five goals with corresponding objectives. The first goal is to implement a facility risk management program. This goal identifies an inventory of worldwide facilities. This inventory assists with the development of a comprehensive risk assessment program. The purpose of this assessment is to develop and promote effective protective measures and strategies. Implementation of the Federal Information Security Management Act of 2002 (The Federal Information Security Management Act (FISMA) of 2002) and the National Institute of Standards and Technology (NIST) cybersecurity programs is essential for the stakeholders to adapt and follow, to perform gap analysis and report findings via a National Annual Report to DHS, and to develop best practice guidance of countermeasures (Office of Infrastructure Protection 2015, Chap. 3, p. 14).

It is crucial to briefly explain the importance of this goal to support the NIPP risk management framework. Central to the NIPP risk management framework is the risk assessment process that incorporates three factors: threat, consequence, and vulnerability. To appreciate these elements, organization should combine the three factors into an equation. Risk equals the combination of threat plus vulnerability plus consequence (or impact). Risk assessments are used to provide reliable and comprehensive data so that security partners can make informed decisions about which risk mitigation measures to implement. In some cases, security partners design risk assessment processes, procedures, methodologies, and tools to meet the specific needs of the facilities they own and operate (Cybersecurity & Infrastructure Security Agency/CISA 2013, p. 17).

The second goal is to create and organize partnerships. There are four objectives associated with this goal. This objective is share information about threats and hazards to facilities internationally as well as domestically; build sector partnerships to implement protection and resilience programs; support continuity programs that protect government operations; and share lessons learned along with any best practices (Office of Infrastructure Protection 2015, Chap. 3, p. 14). GFS security partners include those federal, state, territorial, local, or tribal entities that share in the responsibility for protecting government facilities and their associated elements. Within these sometimes large and complex government entities, security partners represent a wide variety

of facility components that contribute to enhance protection of every facility. Some GFS security partners have different responsibilities, functionality, or expertise based on existing authorities and associated roles. State, local, and tribal governments have the responsibility to implement the homeland security mission, to protect public safety and welfare, and to ensure the provision of essential services to communities and industries within their jurisdictions.

The third goal is to integrate government facility protection with the DHS mission. The supporting objectives are to link the NIPP to the initiatives promoted by the Federal Emergency Management Agency (FEMA). This objective links the NIPP to the National Response Framework (NRF). The importance of the NIPP to NRF alignment is described in the following quote: "The NRF is a guide to how the Nation responds to all types of disasters and emergencies. It is built on scalable, flexible, and adaptable concepts identified in the National Incident Management System (NIMS) to align key roles and responsibilities across the Nation" (FEMA 2016, p. i). The next objective aligned with this goal is to enhance planning and protective measures to align the GFS sector with the National Terrorism Advisory System (NTAS), the Continuity of Government Readiness Conditions (COGCON) system, and the Homeland Security Information Network (HSIN). These key alignments provide the structure needed to alert GFS stakeholders of impending threats, preventative measures, lessons learned, and mitigation best practices. The final objective of this goal is to implement incident management activities (Office of Infrastructure Protection 2015, Chap. 3, p. 15).

The fourth goal is to promote enhanced capabilities of the GFS. "The four objectives that support this goal are to support awareness and understanding of the risks to the GFS are To improve cyber and physical resilience through research and development; Continually develop a GFS SSP to further align with the NIPP; And to promote Executive Order 13636 directed programs of the NIST Cybersecurity Framework and the DHS Critical Infrastructure Cyber Community C^3 (C-Cube) Voluntary Program (Office of Infrastructure Protection 2015, Chap. 3, p. 15)." This GFS goal includes more than just facilities. It also includes physical assets, cyberinfrastructure, positions, and functions that can be essential to the operation of GFS.

The final GFS goal is to maximize and economize the use of resources for GFS protection. The three objectives are to determine GFS priorities and requirements for GFS protection, to enable or facilitate protection for those GFS facilities which are deemed nationally critical, and to outline and decrement countermeasures and mitigation strategies (Office of Infrastructure Protection 2015, Chap. 3, p. 15). A risk assessment is used to provide reliable and comprehensive data to inform risk mitigation decisions. FEMA in 2005 published "Risk Assessment: A How-To Guide to Mitigate Potential Terrorist Attacks Against Buildings" It provides a generic roadmap to basic risk assessment and mitigation methodology (FEMA 452 2005)."

The five sector goals use the goals of the NIPP 2013 and the joint national priorities (JNP). The JNP priorities are risk management, partnerships, capabilities, security, and resilience (Office of Infrastructure Protection 2015). The critical purpose of prioritization is to assist with decrementing resource allocation decisions. GFS stakeholders must determine where protection programs are instituted, the appropriate level of investment in these programs, and which protective measures offer the highest return on investment. Because resources for GFS protection are limited, risk analysis based on practical information must be required before the implementation of sound priorities (Office of Infrastructure Protection 2015, p. 31).

Government Facilities Sector Assets

It is important to outline the diversity of GFS assets. The primary area of the sector is approximately 9000 US federal government facilities encompassing an excess of "3 billion square feet of space and 650 million acres of land" (CIRC 2003a). PBS (2017) manages more than 370 million square feet of workspace in over 8,600 facilities. "The Department of Defense is still one of the Federal government's larger holders of real estate managing a global real property

portfolio that consists of nearly 562,000 facilities (buildings, structures, and linear structures), located on over 4,800 sites worldwide and covering over 24.9 million acres (DoD Base Structure Report FY 2015 Baseline 2016, p. 2)." These numbers do not include the Department of Defense bases, installations, and facilities.

To demonstrate how difficult it is to protect the GFS, consider that before the Interagency Security Committee (ISC) was established under Executive Order 12977 by Clinton, there were no minimal physical security standards for nonmilitary facilities. It was the absence of rigid standards that allowed a 1995 domestic attack on the Alfred P. Murrah Federal Building in Oklahoma City, Oklahoma, resulting in 168 deaths.

Since 1995, The ISC published policies, standards, and best practices for stakeholders of nonmilitary facilities to follow. In 2003, President Bush, G. W. issued Executive Order 13286. This order transferred the ISC from GSA to DHS (EO 13286 2003). Working with the FPS and the security stakeholders of the federal executive agencies, the ISC provides governance to the GFS. The preponderance of the 2018 standards and guidelines are exempt from public release under the Freedom of Information Act (5 U. S. C. 552). Organizations requiring access to these documents can request them from DHS.

The guidelines focus on the physical security aspects of protection. The ISC has a convergence subcommittee. This subcommittee develops mechanisms to support federal agencies' integration of information management controls with security programs. The Internet of things (IoT) has over the years gained importance to the resilience of our infrastructure (see IoT in this encyclopedia). The resulting threats to physical and cyber systems become an increasing priority for the new threats that will adversely impact the GFS facilities (National Institute of Standards and Technology Interagency 8228 2019, p. iv).

The current devices are the result from the convergence of physical security systems operating on information technology (IT), and operational technology (OT) environments present unique security challenges (NISTIR 8228 2019, p. 5). The IT environment is "...a discrete set of information resources organized for the collection, processing, maintenance, use, sharing, dissemination, or disposition of information..." (OMB Circular A-130). The OT environment for this discussion is "...any system that gathers information on an industrial process and modifies, regulates, or manages the process to achieve the desired result..." (NCCIC 2019, p. 4).

The importance of the convergence subcommittee is to provide a nexus between physical and cybersecurity across these environments. The concept of this subcommittee is to identify issues and challenges agencies may have with security programs and work in collaboration with NIST to integrate physical and cybersecurity management controls. In 2012, the DOC advocated for the use of DHS security standards and risk management applications for all off-installation leased space managed by DoD and all DoD occupied spaced in buildings owned or operated by the US General Services Administration (GSA) (Applied Research Associates Inc 2016).

The role of the ISC is to assist the federal stakeholder in the protection of the facilities within their purview. The ISC centralizes the review of risk management, emergency response, business continuity, physical, logical, and personnel security systems to provide standards and best practices, which will assist agencies in improving their protection of assets and at the same time ensure efficiency. In 2015, the ISC advocated converging traditional security and information technology disciplines in a coordinated effort to secure GFS assets (ISC-CVS 2015).

GFS Sub-sectors

PPD-21 required that the education facilities and the national monuments and icons sectors are within the purview of the GFS (PPD-21 2003). The Office of Safe and Drug-Free Schools (OSDFS) an organization of the US Department of Education (ED) serves as the SSA for the education facilities sector (EFS). The US Department of the Interior (DOI), as the NMI Sector-Specific Agency (SSA), liaises with the DHS Science and Technology Directorate and the Executive Office of the President's Office of Science and Technology Policy (US Department of the Interior 2010, p. 3).

Education Sub-sector

In 2010, an SSP was released by the education facilities (US Department of the Interior 2010 cover). "The EFS covers all public, private, and proprietary education facilities (US Department of Education 2011, p. 1)." These facilities have two distinct institutional types. These types are prekindergarten (PreK) through 12th grade (PreK–12) and higher education campuses. A key ED organization is readiness and emergency for school (REMS) technical assistance center. An essential function of REMS is to facilitate grants and provide safe schools and emergency preparedness programs to the education community.

As mandated by the NIPP of 2009 and the GFS SSP of 2010, the EFS SSP aligns its planned initiatives with the GFS guidance (US Department of Education 2010 EXSUM). This alignment is within the primary sub-sector goal to continue sector progress in emergency management. This progress includes emergency preparedness for schools and higher education. OSDFS facilitate this progress by providing grants and emergency management training (e.g., prevention, mitigation, response, recovery) for schools and universities (US Department of Education 2010, p. 13). It is through this vision statement the EFS can universally support the diversity of the sector's facilities. In short, the sector's value proposition to its stakeholders is "to encourage a resilience approach to emergency management (US Department of Education 2010, p. 14)."

A deliverable of this office's effort was the preparation of the guide for developing high-quality emergency operation plans for institutions of higher education that was prepared for the US Department of Education under Contract Number EDESE12O0036 with Synergy Enterprises, Inc. The EFS OSDFC works closely with DHS and other federal agencies to address protection efforts. OSDFC also coordinates with national interagency collaborations and SLTT governments and private organizations (US Department of Education 2011, p. 2). One federal interagency collaboration was the 2013 release of the guide for developing high-quality emergency operation plans for institutions of higher education. This institution of higher education (IHEs) guide was created through the cooperative efforts of multiple US government sectors (IHE 2013).

An ancillary initiative was the enactment of the Jeanne Clery Disclosure of Campus Security Policy and Campus Crime Statistics Act (**20 U.S. C. § 1092 (f)). The Clery Center was** founded in 1987 by Howard and Connie Clery following the murder of their 19-year-old daughter, Jeanne, in her dorm (McCallion 2014, p 1)**.** The ED 2016 Edition of the handbook for campus safety and security reporting describes the Clery Act (ED handbook 2016). Numerous laws predicated the Clery Act. The *Higher Education Act of 1965 (HEA) required all postsecondary institutions participating in HEA's Title IV student financial assistance programs to disclose campus crime statistics and security information* (ED handbook 2016, p. 1-1).

The Clery Act amends the requirements of the HEA (Clery handbook 2016, pp. 1-1 to 1-3). Institutions of higher learning except for distant education and foreign institutions must comply with the disclosure requirements of the act (ED handbook 2016, pp. 1-3 to 1-4). "The Clery Act describes that every institution must meet crime statistics and security-related policy. Clery Act requires crime logs for institutions that have a campus police or security departments. HEA requires missing student notification and fire safety requirements for institutions that have at least one on-campus student housing facility (ED handbook 2016, pp. 1-3 to 1-4)." To ensure institutions have the requisite information to perform a risk assessment of the campus, the Clery Act requirements of determining the institution's geography and collecting statistics (ED handbook 2016, pp. 2-1 to 4-12) will assist the institution with applying the NIPP and GFS risk management framework (Cybersecurity & Infrastructure Security Agency/CISA 2013, p. 15) (Office of Infrastructure Protection 2015, p. 17).

National Monuments and Icons Sub-sector

In 2007, DOI released the NMI SSP to ensure that the NMI facilities of other federal agencies and SLTT governments would be aligned and within the purview of GFS and NMI sectors. Three common characteristics define the sector's assets. First, they are a monument, physical structure, or an object. The facilities must represent our nation's heritage, traditions, or values. The final

characteristic is the facility's purpose of memorializing our nation's heritage, traditions, or values (Office of Infrastructure Protection 2007a, 2007b, p. 1). In addition to these three common characteristics of NMI, another factor characterization is that these facilities are open to the public with the minimum of ingress and egress controls, during their hours of operation (Office of Infrastructure Protection 2007a, 2007b, p. 2). Throughout the NMI SSP, the facilities and infrastructure defined as critical infrastructure and key resources or CI/KR. These designations were consistent with the NIPP 2006. This terminology came from homeland security presidential directive-7 (Critical Infrastructure Research Center 2003a, p. 1).

The NMI SSA has a group of authorities that supplement the protection efforts of major federal law enforcement organizations, like the Federal Bureau of Investigation and the Secret Service (US Department of the Interior 2007, p. 56). DOI over the years was given certain legislative authorities to support the agency's protection efforts. A snapshot of some of these authorities is the "Antiquities Act of 1906: Congress passed the Antiquities Act of 1906. This act authorized the President to declare by public proclamation (as national monuments) historic landmarks, historic and prehistoric structures, and other objects of historic or scientific interest" (16 U.S.C. 431).

In 1916, Congress created the National Park Service (NPS) within DOI through an Organic Act for the purpose of preserving specific areas, particularly from development. The General Authorities Act of 1970 (Public Law 91-383, as amended by Public Law 94-458) gave the DOI secretary to designate certain employees of the department as well as officers and employees to act as special policemen within the areas of the NPS. The National Historic Sites Act of 1935 declared as a national policy to preserve for public use historic sites, buildings, and objects of national significance for the inspiration and benefit of the people of the United States. In 40 U.S.C. 6301-6307 provided the Smithsonian Institution's Office of Protection Services the authority to police the buildings and grounds of the Smithsonian Institution (US Department of the Interior 2007, pp. 55–56). The previous listing is a sampling of the authorities given to the DOI. It does provide an abbreviated review of how the SSA provides protection oversight of the sector.

GFS Minor Sub-sectors

Categorization of Facilities and Associated Elements. The minor sub-sectors of the GFS are personnel centric, service-oriented facilities, research and development facilities, storage and preservation facilities, military installations, and space exploration facilities, along with government sensor and monitoring systems (McCarthy 2007 volume 6 number 1). In general, the GFS categorization denotes two distinct types of facilities. The personnel-centric facilities are locations where government personnel work and conduct the business of the government. They have limited public access and typically do not experience large numbers of visitors (Office of Infrastructure Protection 2007e, p. 1). The second type is service-oriented facilities; these facilities provide services to the government and the general public. They experience large numbers of citizens. These facilities typically contain the technical equipment necessary to carry out and deliver government services (Office of Infrastructure Protection 2007f, p. 1).

Federal offices and office building complexes are "government facilities that are categorized based on the main function or purpose of the building or its primary use. Personnel-centric facilities house government personnel in the course of official business or personal pursuits (Office of Infrastructure Protection 2007e, p. 1)." Additionally, data centers, as well as federal SLTT office buildings, are included within this sub-sector.

The courthouse is a minor subsector of the GFS. The subsector includes facilities owned, operated, and leased by all levels of government. The federal court system (FCS) consists of 94 district courts, 13 circuit courts throughout the country, and 1 supreme court located in Washington D. C. These courts may represent two or more facilities (Office of the United States Attorneys 2019). In addition to the federal court system, state, local, tribal, and territorial (SLTT) jurisdictions have the responsibility to enforce state and local laws and ordinances. The scope of these facilities includes all 50 states, 3,043 counties, 19, 372 municipal, and 16, 629 township jurisdictional courts.

The federal court's system security and protection is the responsibility of the US Marshal Service. The Marshal Service established in 1789 (US Marshals Service 2019). The SLTT governments have the responsibility for protecting and securing court fall to the cognizant law enforcement jurisdiction. As such, the NMI 2007 conformed to the NIPP risk management framework of 2006 (Office of Infrastructure Protection 2006, p. 4). This version of the NIPP showed six elements of this framework. These elements are "set security goals; identify assets, systems, networks, and functions; Assess risks; prioritize; implement protective programs; And measure effectiveness (Office of Infrastructure Protection 2006, p. 4)." With the release of the NIPP of 2013, the chevron element of prioritizing was removed (Office of Infrastructure Protection 2013, p. 15). However, within the 2013, version of the NIPP prioritization is included within the measure effectiveness chevron. Realigning the risk management framework assures the identification of high-level outputs or outcomes associated with the national goals and priorities (Office of Infrastructure Protection 2013, p. 20).

Storage and preservation facilities are a complex minor subsector of GFS. These facilities include centers that store records and materials that require permanent protection for historical and lifetime storage, upkeep, and preservation (Office of Infrastructure Protection 2007f, p. 1). The National Archives and Records Administration (NARA) is responsible for the national personnel records and the federal record centers (Office of Infrastructure Protection 2007d, p. 1). The subsector is also responsible for oversight of specialized storage facilities housing precious metal and currency, weapons and ammunition and special nuclear materials, and waste (Office of Infrastructure Protection 2007g, p. 1). The US Mint, the Department of Defense, and the Nuclear Regulatory Agency provide direct oversight over those areas within their area of responsibility.

An important function of NARA is to provide direct oversight of archives and libraries. The National Archives is the repository of US documents (Office of Infrastructure Protection 2007d, p. 1). The sector through NARA has oversight for presidential and federal libraries. The sector includes libraries associated with education facilities. The ED SSP will have direct oversight of college and university libraries by the requirements of the Clery Act. Public libraries would be the responsibility of SLTT governments (Office of Infrastructure Protection 2007d, p. 2).

The US Department of State (DOS) and the customs and border patrol of DHS oversee embassies, consulates, and border facilities measures. The US government has diplomatic relations with about 180 countries. A US mission manages American diplomatic and consular activities (Office of Infrastructure Protection 2007c, p. 1). The Bureau of Diplomatic Security (DS) personnel – who include special agents, engineers, diplomatic couriers, civil service specialists, and contractors – work together as a team to ensure that the state department can carry out its foreign policy missions safely and securely. In the USA, the Bureau protects the Secretary of State, the US Ambassador to the United Nations, and foreign dignitaries below the head-of-state level who visit the United States. DS develops and implements security programs to protect the more than 100 domestic state department facilities as well as the residence of the secretary of state. Lastly, border stations are a "land port of entry" that provide controlled egress from the United States for persons and materials. A border station houses US Customs and Border Protection and other Federal Inspection Agencies responsible for the enforcement of federal laws about entry into or departure from the USA (Office of Infrastructure Protection 2007, p. 2).

Conclusion

Providing services to the citizens of the USA is a core function of the GFS. The sector's complexity requires a wide range of coordination with public and private stakeholders. The sector's facilities educate our nation's population, provide and house facilities that conduct administration of justice activities, and preserve the heritage of our nation. The services provided by the GFS are crucial to the protection and resilience of our nation. One major private sector contribution to this collaboration is the Clery Center. The Clery Center's operation is indicative of the nonprofit and not-for-profit organizations that are crucial to

the GFS accomplishing its vision and goals. The federal sector element relies on the cooperation of SLTT governments. The release of the 2015 GFS SSP enhanced the coordination between all GFS stakeholders. Interested personnel and organizations can now use the GFS SSP freely to give the sector community the governance needed to enhance protective and resilience thinking.

Critical Infrastructure: Nuclear Reactors, Materials, and Waste Sector

Adam D. Williams
Center for Global Security and Cooperation, Sandia National Laboratories, Albuquerque, NM, USA

Keywords
Reactor security · Nuclear materials

Definition

Nuclear reactors provide several key societal benefits – including electricity generation and industrial/medical isotope production – that need to be protected against malicious activities.

SAND2018-9356J. Sandia National Laboratories is a multimission laboratory managed and operated by the National Technology & Engineering Solutions of Sandia, LLC., a wholly owned subsidiary of Honeywell International, Inc., for the US Department of Energy's National Nuclear Security Administration under contract DE-NA-0003525

Introduction

Nuclear technologies provide a range of benefits to the society. These benefits include reduced carbon emission electricity production, seawater desalination, generating radionuclides to serve various medical needs (including cancer treatments), and advanced technological development. As such, these activities and facilities are assessed by the Department of Homeland Security (DHS) to be critical because:

> a significant incident or failure. . .would likely result in extremely high economic costs, major onsite and/or offsite property damage, and evacuations. . .[as well as] long-term cleanup costs and economic damage to the local region. (DHS 2015, p. 9)

Therefore, to ensure these benefits are realized, facilities hosting these technologies fall under the purview of the US Department of Homeland Security's *Nuclear Reactors, Materials, and Waste Sector*. Given that the natural and physical characteristics of nuclear materials pose unique – and potentially catastrophic – consequences, related security and emergency management responsibilities must mitigate such current threats as expanding terrorist capabilities, increasingly sophistical cyber actions, aging equipment (including power grids), and supply chain challenges.

The rest of this paper describes efforts at such protection by focusing on nuclear reactors as a use case. After briefly introducing the need for reactor security, unique challenges, key security concepts, and common themes between different approaches to reactor security are discussed. These challenges, concepts, and common themes are reflective of the larger *Nuclear Reactors, Materials, and Waste Sector* and aid in protecting this critical infrastructure.

What and Why of Reactor Security

Nuclear reactors generate these aforementioned benefits by using the energy released during the rapid and exponentially increasing collisions of atomic and subatomic particles known as nuclear fission. The process of fission has two major products. The first is a large amount of thermal energy, or heat – captured from the fission of nuclear materials (Nuclear materials is a term designated for elements capable of sustaining fission in a controlled chain reaction and is commonly known to consist of uranium, plutonium, and thorium) – that is converted into electricity or used in desalination. The second product results from the change in the atomic structure of the materials that undergo fission – which is how the various radionuclides that support medical and industrial needs are generated.

Two major categories of nuclear reactors manipulate nuclear fission to different ends. The first is known as *power reactors* and is primarily used to generate electricity or for desalination for societal consumption. For example, the United States has 99 operating nuclear power reactors that account for approximately 20% of its domestic electricity production (DHS 2015). Similarly, the International Atomic Energy Agency's (IAEA) Power Reactor Information System (PRIS) reports 450 nuclear power reactors internationally that account for approximately 11% of global electricity production, with the highest nuclear energy-based electricity production of over 70% in France (International Atomic Energy Agency 2018b). Through PRIS, the IAEA also reports more than 50 new nuclear power reactors in various stages of consideration or under construction – including in Belarus, China, Turkey, Russia, and the United Arab Emirates (International Atomic Energy Agency 2018b).

The second major category consists of research reactors that are smaller, produce less thermal power, and are used for a variety of purposes. According to the IAEA's Research Reactor Database (RRDB), there are 225 research reactors worldwide, including 31 in the United States. Research reactors can be used for exploring new nuclear fuel cycles, neutron activation analysis, and educational purposes (International Atomic Energy Agency 2018a). These reactors are also commonly used to generate radioisotopes used in medical

procedures, to include the need for strontium-89, palladium-107, iridium-192, and iodine-125 (or 131) in cancer treatments. In addition, these reactors produce the molybdenum-99 used in medical imaging devices. Research reactors are also used to generate isotopes for industrial uses, to include (but not limited to) iridium-192 and selenium-75 used in industrial radiography, as well as americium-241 for well-logging and commercial/residential smoke detectors. Research reactors are less technically complex than power reactors, require significantly less fuel to operate, use higher-enriched fuel than power reactors, and their designs avoid the high temperatures and pressures of electricity-generating reactors. Research reactors can exist in wide-ranging operational environments, including universities, medical facilities, and commercial campuses around the world (National Academy of Sciences 2016).

To ensure these societal benefits are enjoyed, the efforts to make nuclear reactors, materials, and waste secure and resilient must protect against "[any] deliberate act against a [nuclear reactor] that could directly or indirectly endanger public health and safety through exposure to radiation" (Holt and Andrews 2014). Such deliberate activities include sabotage (either by directly or indirectly adding energy to cause a radiological release), theft (removing materials to use in an offsite radiological release), and unanticipated reactor transients (causing operations to slow/stop and resulting in unacceptable consequences such as loss of profit or reputation) (Please see chapter ▶ "Insider Threat," for further discussion.).

Examples of malicious acts against nuclear facilities include:

- **2012**: Activists entered two Swedish nuclear power plants without being stopped by guards, and four of them hid overnight on a reactor building roof (MacFarlene 2016).
- **2014**: French nuclear power plants were plagued by unexplained drone overflights that challenged existing reactors security measures (Solodov et al. 2018).
- **2014**: An unidentified adversary tampered with turbine lubricant at the Doel Nuclear Power Station in Belgium causing Unit 4 to shut down for 5 months (MacFarlene 2016).
- **2016**: French investigators discovered video surveillance footage of a Doel Nuclear Power Station official in the home of one of the Paris terror attack suspects (MacFarlene 2016).

Unfortunately, these cases highlight the real threat against nuclear reactors and emphasize the need for protection of these critical pieces of infrastructure. In addition to deliberate terrorist acts, the US Department of Homeland Security has recently identified the following risks related to security of both nuclear reactors and other aspects within the nuclear energy sector, to include (DHS 2015, pp. 9–10):

- Natural disasters and extreme weather
- Structural issues of specialized designs and components
- An aging infrastructure and workforce
- Cyberattacks
- Supply chain disruptions
- Nuclear material diversion or mishandling

To that end, the goal of reactor security is to protect people, infrastructure, and the environment from radiological releases caused by malicious acts. Pointedly, nuclear reactor security should be:

> designed to protect three primary areas of vulnerability: controls on the nuclear chain reaction, cooling systems that prevent hot nuclear fuel from melting even after the chain reaction has stopped, and storage facilities for highly radioactive spent nuclear fuel. (Holt and Andrews 2014, p. 1)

Unique Challenges Facing Nuclear Reactor Security

Yet, the special physical properties of nuclear reactors pose a set of additional – and unique – challenges for security and emergency management efforts. The first unique challenge in securing nuclear reactors is the danger related to radioactive materials (Radioactive materials can consist of several species of the same chemical element with different masses whose nuclei are unstable and dissipate excess energy by

spontaneously emitting radiation in the form of alpha, beta, and gamma rays). To achieve their societal benefit, reactors use a subset of these radioactive materials capable of sustaining chain reactions to harness the energy released by fission. By-products of nuclear fission are atomic fragments with unstable nuclei, which is the physical phenomenon that makes them radioactive. Radioactive materials also carry particular, severe, and psychologically fear-inducing characteristics related to acute (e.g., radiation poisoning) and delayed (e.g., latent cancer) human health effects. Despite the fact that materials used in power reactors is not viable for military use, nuclear materials are often conflated with the danger associated with nuclear weapons. The dangers attributed to radioactive materials – both factual and perceived – create a higher standard for reactor security beyond that traditionally expected for other critical infrastructure.

These radioactive materials also need special handling equipment, rules, and processes to ensure that these materials – and the energy they produce – are used in a controlled manner. One example of special handling equipment are reactor cooling systems that consist of both active (e.g., using energy to dissipate heat in the reactor like forced flow cooling loops in nuclear power plants) and passive (e.g., allowing heat to dispel naturally as with cooling towers) mechanisms. Another example of special handling equipment relates to the need to store the highly radioactive nuclear fuel that has been used in a reactor. So-called spent nuclear fuel (in some arenas, this term is called "used nuclear fuel") is most commonly stored in large pools of water or in large concrete casks. As indicated by Holt and Andrews (2014), in addition to the nuclear reactor itself, another challenge is that each of these pieces of special handling equipment also requires protection from malicious activities.

Nuclear reactors must also safely function in multifaceted operational environments and handle physical environments with extremely high temperatures and pressures. Nuclear reactors must also navigate long operational lifetimes (often 40–60 years for power reactors) with the industrial emphasis on safety, a significant emphasis on production, and where, according to one nuclear security expert, "every dollar that a facility manager spends on protection is a dollar not spent on revenue-generating production" (Bunn 2005). Operations at nuclear reactors must also survive under the scrutiny and influence of fluctuating public opinion over the correct balance between the societal benefits provided and risks (real and perceived) accepted. For power reactors, their infrastructure footprint and larger number of moving parts present a wider range of potential threats, while the large workforce also poses potential conflicts for security-related activities. For research reactors, their smaller infrastructure footprint and smaller number of moving parts present less of a range of potential threats, but their proximity to other operations can result in less control over access to the reactor or its special handling equipment – which represents a special set of potential challenges to reactor security. Each of these unique challenges are dimensions that must be accounted for when protecting nuclear reactors.

Reactor Security: Key Concepts

Despite these threats and challenges, efficient and effective reactor security is based on several key concepts. The first key concept is that reactor security starts with the regulations established at the national level. Most commonly, a designated competent authority drafts such regulations, communicates them to individual facilities, and ensures their enforcement (International Atomic Energy Agency 2017a). Each facility with a nuclear reactor is then responsible for translating these regulations into site-specific policies and procedures that align with its unique operational environment. Consider, for example, regulations and policies that relate to the different security zones within (and around) nuclear reactor facilities. More specifically, in the United States:

> The [nuclear reactor] sites are divided into three zones: an "owner controlled" buffer region, a "protected area," and a "vital area." Access to the protected area is restricted to a portion of plant

> employees and monitored visitors, with stringent access barriers. The vital area is further restricted, with additional barriers and access requirements. (Holt and Andrews 2014, p. 1)

While the national-level competent security authority mandates the existence of these zones, the nuclear reactor facility is responsible to operationalize them with the proper security technologies and procedures. This is an example of the importance of clearly and effectively communicating and implementing the different security-related responsibilities between national-level and facility-level nuclear stakeholders.

The second key concept relates to *preventive measures* to protective nuclear reactor facilities. These measures seek to stop malicious activities to reactor facilities before undesired consequences are experienced. Some preventive measures seek to *detect* malicious activities in order to initiate a mitigation, or response, and can consist of such measures as video cameras, motion sensors, closed-circuit television systems, and human observation. Another type of preventive measure seeks to *delay* malicious activities through the use of physical barriers (e.g., bullet-resistant surfaces within the reactor facility) or administrative controls (e.g., access requirements into the reactor building). Preventive measures also include efforts to increase trustworthiness among facility personnel and can include (but are not limited to) background investigations, highly trained security officers, and programs that incentivize adhering to security procedures (For further discussion on detection, please see chapters ►"Intrusion Detection Systems," ►"Physical Security: Interior Applications," or ►"Physical Security: Video Surveillance, Equipment, and Training".).

Mitigation measures – the third key concept – seek to contain or reduce the severity of undesired consequences resulting from malicious activities. For nuclear reactors, the primary mitigation for suppressing such consequences is the containment structures (meter-thick steel-reinforced concrete) enveloping the reactors. Similarly, reactor facilities have safety systems in place for quickly stopping the nuclear chain reaction occurring in the reactor. In this case, the control room for reactor operations – more specifically, the ability to drop control rods into the reactor or to flood the reactor core – represents another mitigation measure. Additionally, the existence of different "security zones" represents yet another mitigation measure by increasing the distance between the results of a malicious activity against the reactor and subsequent dangers to the public.

Common Themes and Guiding Principles

Despite the lack of global standards (MacFarlane 2016), there are common themes and lessons to be learned from various applications of these key concepts that can serve a strong foundation for reactor security. First, nuclear reactors face a unique set of challenges to effective security above and beyond those traditionally associated with other types of critical infrastructure. Second, effective reactor security is predicated on the combination of strong regulatory standards at the state level, performance requirements established by the competent security authority, and implementation of related technological and procedural measures at the facility level. Third, reactor security must be effectively coordinated across facility operations and properly employed for sustained long-term success.

In addition, strong reactor security can be built using a few long-established guiding principles supported by both international best practices – including from the IAEA's Nuclear Security Series (International Atomic Energy Agency 2017b) and the World Institute for Nuclear Security's Best Practice Guides (2018) – and US-based documents (e.g., US Nuclear Regulatory Commission (2017) and US Department of Homeland Security (2015) regulations and reports). First, the safety principle of *defense-in-depth* describes the benefits of creating multiple, concentric layers of protection measures around nuclear reactors can enhance robustness reliability and resiliency of security performance. Second, the principle of *balanced protection* describes the importance of equivalence between protection

measures that compose a security layer. Moreover, this second principle describes the importance of removing as many "weakest links" as possible – ensuring that similar access controls are in place at the main facility entrance and the loading dock, for example.

Third, the principle of taking a *graded approach* to reactor security describes how the selection and implementation of both technological and administrative protection measures are scaled to align with the operations of the nuclear facility – nuclear power plants need a larger security infrastructure than research reactor facilities, for example. Fourth, the guiding principle for reactor security to be *risk-based* describes how decisions related to the selection and implementation of protection measures are quantitatively mapped to clearly define undesired consequences and the current understanding of potential malicious activities against the facility.

Conclusion

Reactor security is a necessary – albeit complicated and complex – aspect of ensuring that the economic, public health, and societal benefits continue to be enjoyed without significant radiological impact to the environment. The common themes and guiding principles for reactor security discussed above are consistent with the risk mitigation strategies and goals provided in the DHS sector-specific plan (DHS 2015), which include:

- Establishing robust collaboration/communication channels and protocols
- Identifying sector-specific threats and vulnerabilities to enable a risk-informed approach
- Developing programs and measures to cost-effectively reduce physical/cyber risks
- Supporting planning and risk mitigation for coordinated response and rapid recovery
- Promoting continuous learning and adaptation to reduce nuclear risks

Taken together, leveraging these common themes and guiding principles can enable strong and sustainable security and emergency management efforts not just for nuclear reactor facilities but also for the larger set of nuclear-related pieces of critical infrastructure. More specifically, reactor security helps support the DHS nuclear sector vision to "support national security, public health and safety, economic stability by enhancing. . .the security and resilience of the Nuclear Sector in an all-hazards environment" (DHS 2015, p. 30).

Critical Infrastructure: Transportation Systems

Richard R. Young[1] and Gary A. Gordon[2]
[1]School of Business Administration, Capital College, The Pennsylvania State University, Middletown, PA, USA
[2]Emergency Management Department, Massachusetts Maritime Academy, Buzzards Bay, MA, USA

Keywords
Security · Resilience · Natural disasters · Manmade disasters · Transportation infrastructure · Transportation modes

Definition

Transportation infrastructure is the collection of rights-of-way, terminals, maintenance support facilities, and communications and control fixed assets necessary for the movement of goods and people from one location to another. Its protection is found in the means of preventing its damage or destruction but also in those activities that mitigate any potential damage in order that the infrastructure be returned to service in the most efficient and effective manner.

Introduction

Protecting transportation infrastructure in the United States requires an understanding of its ownership, the characteristics of each mode, the relevant governing political jurisdictions, and various protective approaches including public policy initiatives. Moreover, there is the realization that the topic of infrastructure is bifurcated into physical and informational categories, again each with particular modal variations and operating characteristics.

Infrastructure ownership can be divided between the public and private sectors; however, because transportation exists as a system, these normally operate in a nearly seamless fashion as both passengers and cargo may traverse both between points of origin and those of destination. Again, because transportation is a system, multiple modes may be utilized as well as multimodal transportation activities and more recently by the long-term growth in intermodal services. Where the matter becomes more complex is with those situations where multiple modes may share the same rights-of-way or facilities or be in close proximity. An example of this within the same mode are where Amtrak, the National Rail Passenger Corporation, shares trackage with Norfolk Southern, a freight railroad operating in the private sector. There are also instances of Amtrak owning tracks that are immediately adjacent to those of CSX, another freight railroad, or light-rail operated by the Port Authority Trans Hudson (PATH) in greater New York/New Jersey (Plant and Young 2007). A most frequently found situation is where highways and railroads operate in close proximity such as with parts of the Interstate 95 corridor.

This entry shall endeavor to address protecting the infrastructure associated with railroads, roads

and highways (aka motor carriage), maritime transport including both inland waterways and open sea, pipeline, and aviation. This is an extensive topic, and the reader is directed to the modal-specific entries found elsewhere in this encyclopedia for in-depth coverage.

Differentiating Links and Nodes

Infrastructure includes terminals and intermodal connections that logisticians term as nodes and rights-of-way connecting those nodes known as links but also maintenance facilities, administration buildings, classification yards, and communications towers for traffic control. As further detail, terminals need to be thought of as those points where transportation services are accessed. Rights-of-way need to be built over a range of geographies; hence, they require bridges, tunnels, culverts, and dredged channels. Rights-of-way exist as expanses of land for carrying rail lines and roadways but also as sea-lanes, air corridors, and subterranean routes carrying pipelines (Plant and Young 2007; Talarico et al. 2016).

There is a range of information-related infrastructure components that continue to grow as technology advances. In earlier times, these marked safe routes of travel, the most obvious of which would be lighthouses, but were later joined by buoys and even later by traffic lights and railway signals. Aviation is now controlled by air traffic control systems, and all forms of information-related infrastructure have become digital combining robust communications capabilities as well (Edwards and Goodrich 2013).

Transportation as a Derived Demand Activity

With few exceptions, the demand for transportation within any mode is derived from the demand for the underlying goods or for the need of people to be transported from a place of supply to one of need. As the population migrates and available products proliferate, the demand patterns also shift. Existing infrastructure may need to be expanded or even new infrastructure built. Moreover, some existing infrastructure may need to be de-emphasized. However, a hallmark of transportation infrastructure is that it may see service for a period spanning a century or more; hence, the priorities assigned to it at one point may no longer be relevant at a later date (Garrison and Levinson 2014).

Most people do not think about transportation infrastructure despite their being dependent upon the service it enables. While it is "just there," it is also expected to be "just there" whenever someone needs to travel from point A to point B or when they have some form of material or service need in everyday life. This is to say that transportation infrastructure is largely invisible until it represents an inconvenience.

Unimodal and Multimodal Considerations

Various modes have different requirements for infrastructure but also differing ownership and maintenance needs. For example, airlines require significant investment in terminals and air traffic control systems; however, the former, while requiring significant acreage, are remote from one another. Airlines and marine transportation are similar in that there is sizeable investment at origins and destinations; there is no private ownership of their rights-of-way, specifically air corridors and the open sea (Garrison and Levinson 2014).

In contrast, railroads are required to own their own rights-of-way (although there are exceptions where ownership is a government unit, especially with regard to passenger railroads) and incur major initial investment as well as ongoing maintenance costs. While each mode has its own particular infrastructure requirements, each of those components needs to be protected from both natural and man-made harm.

Protection from What?

Infrastructure needs to be protected from both natural and man-made incidents; however, these

Critical Infrastructure: Transportation Systems, Table 1 Taxonomy of threats

	Natural events	Man-made events
Rapid onset	Lightning strikes	Accidents
	Earthquakes	Terrorist attacks
	Floods	
	Tornados	
	Flash floods	
Moderately rapid onset	Hurricanes	
	Blizzards	
	Ice storms	

Source: Adapted from Young and Peterson (2014)

may occur across a wide scale of magnitude. A taxonomy of such incidents is found in Table 1 where the speed of incident onset is also an important consideration.

The variables of speed of onset, location, scale, timing, and whether the incident is natural or man-made have a clear bearing on how and to what extent a particular element of infrastructure needs to be protected. Note, too, that protection needs to be considered both when the particular asset is built and during its useful life.

Several factors are related to the need to protect transportation infrastructure and while this list is not intended to be exhaustive, they nevertheless need to be considered (Young and Peterson 2014):

1. Speed of onset is to also suggest a modicum of unpredictability with regard to timing, magnitude, location, and frequency (or regularity of threat).
2. The extent to which multiple infrastructure components are affected at any particular time. An example would be the loss of a specific bridge plus a nearby power station, both used by an electrified commuter railroad.
3. High stakes – in other words, human life is threatened, or are people's physical well-being adversely affected
4. The infrastructure component is either so large or complex that its damage or destruction will require a lengthy period of time to repair or replace
5. The infrastructure component is in a remote location where equipment, personnel, and needed materials are not easily accessed?
6. There may be cascading impacts such as when a tsunami is triggered by an earthquake or that a terrorist organization may take advantage of a natural disaster occurrence.

Public Policy and the National Infrastructure Protection Plan

Through much of US history, the protection of infrastructure has been highly fragmented with the key exceptions being during wartime when key elements warranted specific extra protection as was the case with those port areas that were embarking troops or war materiel. A specific case during World War II was the Pennsylvania Railroad's Horseshoe Curve in Western Pennsylvania, which at the time handled a disproportionately high volume of freight destined to the European front. Its importance was such that Germany actually landed a team of saboteurs tasked with the curve's destruction – fortunately the plan never came to fruition, the agents were captured, tried, and executed (Plant and Young 2007).

In the post-9/11 era, concern over all manner of terrorist activity prompted the formation of the National Infrastructure Protection Plan (NIPP 2013). With the realization that there is so much infrastructure deemed critical, both public and private sector owners and operators have been encouraged to make risk-informed decisions in order to arrive at the most effective solutions for allocating the necessary resources to protect the infrastructure. To take a direct quote from the NIPP:

> While individual entities are responsible for managing risk to their organization, public-private partnerships improve understanding of the threats, vulnerabilities, and consequences of how to manage them through the sharing of indicators and practices and the coordination of policies, response, and recovery activities. (NIPP 2013)

With the number of public and private entities involved, it is reasonable to recognize that different entities will have different tolerances

for risk depending on their specific business plans, resources, and regulatory environments. Protecting infrastructure, therefore, becomes a matter of applying risk management practices of both government and industry within the constraints of available resources and incentives and the range of consequences (Lee 2009).

The NIPP needs to be considered as the cornerstone for transportation infrastructure protection. To paraphrase its key tenets:

1. Risk needs to be identified and managed in a coordinated way in order that security and resilience resources can be efficiently allocated. Security and resilience need to be considered joint being the security can be thought of as preventing an occurrence and protecting the infrastructure element as well as limiting the impact in the event of an occurrence.
2. The understanding and addressing of risks from cross-sector dependencies and interdependencies is essential. It is essential that different sectors understand one another. For example, the nation's railroads operate as individual corporations, but they also function as a network. This means that during the normal course of business, they interchange freight cars in order that a shipment can move from one coast to the other by transiting the rails of multiple firms. In similar fashion during, for example, a natural disaster or a man-made act such as sabotage, entire trains or individual freight cars can be routed on competitors' lines in order that the disruption to the supply chain is minimized.
3. Cross-community information sharing is essential. Cross-community is defined as public and private sectors but also across industries. Transportation is a derived demand activity that means that there is an inherent relationship between transportation service providers and their respective shippers and consignees.
4. The importance of particular units of critical infrastructure transcends national boundaries thus requiring cross-border collaboration, mutual assistance, and other forms of cooperative agreements.
5. Many if not most supply chains are now global, meaning that the interdependency between US interests and those of foreign partners is inseparable. Firms are increasingly aware that their success may not just be dependent upon their tier-1 suppliers but that tier-2, tier-3, and tier-n may pose a considerable previously unrecognized risk. Consequently, with that many tiers of concern, the vulnerability can be significant as transportation infrastructure embracing multiple modes are employed. Between transporting raw materials, semifinished components for further assembly, and finished goods, today's products may wind up traveling thousands of miles before ever reaching the consumer (Supply Chain Council 2017).
6. Security and resilience need to be considered when assets, systems, and networks are being designed. Consideration must be given to determining the most effective and efficient approaches to identify, deter, detect, disrupt, and prepare for threats and hazards, mitigate vulnerabilities, and minimize their consequences. Building resilience into the infrastructure can be thought to be a, if not the, major consideration (McDougall and Radvanovsky 2008).

The NIPP received a major boost when the issue of critical infrastructure was emphasized in the Presidential Policy Directive 21 (PPD 21) in 2013. PPD 21 unscored the importance of critical infrastructure as a key element in national security but also for the nation's economic well-being as well. Moreover, it charged 11 key federal agencies with developing critical infrastructure security and resilience functional relationships for 16 industry sectors, evaluating the public-private partnership model, identifying systems requirements to enable information sharing, developing a situational awareness capability, and the creation of a national research and development plan. While the term critical infrastructure encompasses a broad spectrum of assets, the key agencies of interest in this encyclopedia entry are the Department of Homeland Security and the Department of Transportation, specifically the Transportation Security Administration (TSA) (PPD-21 2013).

Cataloging Critical Infrastructure and Key Resources

Before being able to address intermodal infrastructure, the magnitude of the nation's transportation infrastructure needs to be assessed on a mode-by-mode basis including the types and quantities of assets required by each, identification of the owners, whether such assets are capacity constrained, and the interrelationships existing between them. The details for beginning such discussion are found in Table 2.

Of particular interest to transportation infrastructure is the often expensive elements that include bridges, tunnels, and the information and control systems necessary for controlling the flows of traffic across the network. The details for these are found in Table 3.

The investment in transportation infrastructure is immense; hence. Even the task of arriving at some quantitative measures is a daunting one. Nevertheless, such is necessary in attempting to understand the nature of US infrastructure and to determine the enormity of the undertaking in protecting it. Table 4, using an assortment of information sources, both public and private, seeks to establish such detail.

Transportation as Networks: Multimodalism and Interdependence

In the above table, there are several notes concerning modes of sharing rights-of-way, terminals, and other infrastructures. While this does pose problems with regard to statistics, it also means that multiple entities will need to address the risk assessments as well as determine the priorities that must be addressed with respect to security and resiliency. Up to this point, the issue of intermodalism and multimodalism have not been addressed; however, these themes are increasingly cogent given, for example, that many truckers now rely on the railroads for their long-distance hauls and the ocean marine carriers are highly dependent on them for the inland movement of containers, both for export and import (Garrison and Levinson 2014; Price and Hashemi 2016).

Understanding the NIPP Framework

The foregoing discussion assessed in broad terms the transportation infrastructure both qualitatively and quantitatively. Because transportation infrastructure has such long useful lives, most protective measures will be retrofitting, often when major maintenance is being undertaken. Moreover, lesser maintained and deteriorated infrastructure makes for more attractive targets for terrorists and more subject to damage from natural disasters than well-maintained infrastructure. The following, shown below as Fig. 1, is a visual portrayal of the NIPP framework and is useful for guiding discussion.

Note that this framework was developed for broad application across all sectors of the economy and can be used in all geographic regions and by a wide range of partners. As with the discussion on transportation infrastructure, there may be government or private sector owners and/or operators involved, and both are always stakeholders. This means that using the model to establish priorities requires a public-private partnership whereby risk is not only assessed, but investment is considered along with the potential use of alternative assets and resources. The NIPP makes a critical point when it states that:

> Risk management enables the critical infrastructure community to focus on those threats and hazards that are likely to cause harm, and employ approaches that are designed to prevent or mitigate the effects of those incidents. It also increases security and strengthens resilience by identifying and prioritizing actions to ensure continuity of essential functions and services and support enhanced response and restoration. (NIPP 2013)

Step 1 of FEMA's critical infrastructure risk management framework speaks to the establishment of goals and objectives that are established at the sector level; however, the most difficult and perplexing aspect of transportation in general and its infrastructure in particular is that it touches every aspect of the economy and in all manner of the health and well-being of the population. There is no sector that is unaffected by transportation inasmuch as it affects food, communications, clothing, shelter, education, energy, finance,

Critical Infrastructure: Transportation Systems, Table 2 US transportation links and nodes infrastructure and its ownership

Mode	Right-of-way	Ownership	Terminal facilities	Ownership	Notes
Aviation	Air corridors	Federal government	Hub airports	State and local government; quasi-governmental authorities	
			Secondary commercial airports		
			General aviation airports	As above plus private ownership	
Inland waterway	Dredged rivers	Federal government	Barge terminals	Private ownership	[a]
	Canals	Federal and state government	Ferry terminals	State and local government; quasi-governmental authorities; private ownership	
Ocean maritime	Dredged rivers and harbors	Federal government; state and local government	Container terminals	Ports authority and private ownership	[b]
			Bulk terminals		
			Cruise and ferry terminals		
Pipeline	Petroleum	Private ownership	Terminals and pumping stations	Private ownership	
	Natural gas				
	Chemicals				
	Water	State and local government, quasi-governmental authorities; private enterprise		State and local government, quasi-government authorities; private enterprise	[c]
Railroad – freight	Main lines	Private ownership although some government ownership exists	Railyards, intermodal terminals	Private ownership	[d]
	Secondary lines				
	Branch lines				
Railroad – Passenger	Main lines	Federal, state, local and quasi-governmental authorities	Stations, railyards	Federal, state, local, and quasi- governmental authorities	
	Secondary lines				
	Branch lines				
Roads and highways	Interstate limited access	State and local government; quasi-governmental authority, some private sector (toll roads)			[e]
	Main arterials				
	Secondary				

Notes:
[a]The majority of barge traffic is for bulk materials; hence, loading/unloading is at shipper or consignee facilities
[b]Port size may vary considerably depending on channel depth and terminal capacity
[c]Excluded are service distribution lines to individual homes and industry
[d]Some branch lines may be owned by local or regional governments with operations leased to others
[e]Municipal streets intended for local traffic are excluded

Critical Infrastructure: Transportation Systems, Table 3 US transportation: major elements and information infrastructure (excludes rights-of-way)

Mode	Major infrastructure	Ownership	Information infrastructure	Ownership	Notes
Aviation	Runways	State and local government, quasi-governmental authorities, private ownership	Air traffic control system	Federal government	[a]
Inland Waterway	Locks	Federal government, quasi-governmental authorities	Aids to navigation (e.g., buoys), lock traffic control systems	Federal and state government, quasi-governmental authorities, private enterprise	[b]
Ocean maritime			Aids to navigation (e.g., buoys and lighthouses)	Federal government, private industry	[c]
			Traffic control systems		
Pipeline	Booster stations	State and local government, quasi-governmental authority, private ownership	Traffic control systems	Private ownership	
Railroad – freight	Large-span bridges	Same as under right-of-way in Table 2	Communication and signaling systems	Private ownership	[d]
	Secondary bridges and culverts		Freight car location systems	Private ownership	
	Tunnels				
Railroad – Passenger	Large-span bridges	Federal, state, local, and quasi-governmental authorities	Communication and signaling systems	State, local, and quasi-government authorities	
	Secondary bridges and culverts				
	Tunnels				
	Electrified line catenary or third rail				
Roads and Highways	Large-span bridges	State and local government; quasi-governmental authority	Traffic control systems	State and local government, quasi-governmental authorities	
	Secondary bridges and culverts				
	Tunnels				

Notes:
[a]Ground traffic control systems are maintained locally
[b]Waterways may be marked by government-owned aids to navigation (ATONs) or in industry-maintained waterway, as with many bulk terminal facilities, by private aids to navigation (PATONs)
[c]Government-operated traffic control systems are used in busy ports and crowded waterways
[d]North American railroads employ radio-frequency identification systems for locomotives and cars. Information exchange between railroads is governed by a joint venture for which the railroads are owners

Critical Infrastructure: Transportation Systems, Table 4 Key US infrastructure components by mode

Mode	Type	Number	Notes
Aviation	Hub airports plus those for commercially served communities	5,388	Usually operate some general aviation
	General aviation airports	19,500	
Inland waterway	Canal miles	25,500	
Ocean maritime	Ports	179	
	Bulk terminals	Not differentiated	
Pipelines	Petroleum, petrochemical, and natural gas	2,400,000	
Railroads – freight	Track miles	223,000	Does not include miles, freight railroads operate over passenger railroad-owned tracks
	Bridges	100,000	Size not differentiated
Railroads – passenger	Track miles	21,356	Passenger railroads most often tenants on freight rails
	Bridges	1,414	Size not differentiated
Roadways	Interstate and national highway miles	160,000	
	Total miles	2,678,000	Includes only paved road surface miles
	Bridges	604,000	Size not differentiated

Critical Infrastructure: Transportation Systems, Fig. 1 Critical infrastructure risk management framework. (Source: Emergency Management Institute, FEMA)

utilities, and services. Services can be interpreted as private sector of government services that would include defense, police and fire protection, and even entertainment. The purpose here is not to set goals and objectives but to raise an awareness of the difficulty such a task can be with a sector that is so pervasive (NIPP 2013).

Step 2 was essentially undertaken on a macro basis in Tables 2 and 3. Key is that the description reads "identify assets, systems, and networks" given that individual assets need to function as components within systems and networks. Note that the term *systems* is meant to denote a group of assets working together as a whole and that networks are groups of systems functioning together. In a transportation example, a container yard within a port area is a particular asset, whereas adding the containership, the berths, and the gantry cranes together is the container shipping system when linked with other ports. To view such within the structure of a network, one must add the highway and rail systems that access a given port area. The partners will each have a different view of the meaning of criticality based on the respective risks involved which mean those that are required for maintaining continued operations for the delivery of goods and services to their customers (NIPP 2013).

Step 3 requires an understanding of three terms that bespeaks the need for protection:

1. Threats – natural or man-made occurrences that have the potential to harm life, information, operations, the environment, property, and the overall economy.
2. Vulnerability – some feature the leaves an asset open to exploitation or susceptible to a specific hazard.
3. Consequence – the effect that an event or incident may have including any potential cascading effect.

Combined, these provide the basis for assessing and analyzing risk. While it is advocated that each of the many stakeholders engage in this process, the reality is that it is a complex and messy affair given the large number of participants each with a different set of priorities as well as risk tolerance and financial objectives. Moreover, the complexity increases exponentially as the scope of a potential incident or event increases (NIPP 2013). For example, the loss of a single highway overpass on a rural highway in Central Pennsylvania will be very different than the loss of an interstate highway span crossing the Mississippi River. Even with such a simple comparison, the importance of that Pennsylvania incident would be different should that road be the major access to an army installation such as Fort Indiantown Gap.

Step 4 requires the actionable plans be implemented. There are no silver bullets available because identifying, detecting, disrupting, and preparing for threats and hazards can be expensive because they require personnel, physical assets, and, in many cases, the application of technology needed to both enhance security and increase resilience (NIPP 2013, Lee 2009). Examples of these in a transportation venue would include:

1. Using security protective measures to detect or delay an attack or intrusion. Several Class I railroads have begun using drones to surveil those miles of right-of-way that transit sparsely populated and remote areas. With regard to natural disasters, airlines for many years have staffed their own weather services in cooperation with the National Oceanographic and Atmospheric Administration. Moreover, Walmart, the retailer but also the operator of a very large private truck fleet, has similar resources.
2. Detecting malicious activities that threaten critical infrastructure and related operations and systems across sectors. BNSF Railway and others have engaged private citizens in their Citizens for Rail Security effort, which functions as an enlarged neighborhood watch (Young, Gordon, and Plant, p. 178). Moreover, the US Coast Guard participates in America's Waterway Watch where recreational boaters are encouraged to "see something, say something" whenever they detect activities that seem out of place (USCG Aux 2018).
3. Implementing intrusion detection and vetting measures for sensitive and mission-critical activities to prevent unauthorized access.

Implementation of the Transportation Workers Identification Card (TWIC) endeavors to credential respective personnel. In more critical activities, such as data centers and most truck terminals, specific identification measures are now commonplace and go beyond simple picture identification initiatives and may include biometric and fingerprint identification (Edwards and Goodrich 2013).

4. Monitoring facilities and networks potentially targeted for attack. Aside from the traditional closed-circuit TV monitoring that has been around for decades, more sensitive locations are installing geofencing technology that uses RFID tags to determine what or who is accessing a given area as well as those that are moving off their intended routing (Young et al. 2017).
5. Monitoring cyber systems for potential incursions into control systems such as air traffic control, train control systems, and pipeline traffic management. Defense-sensitive firms have for some time employed software that cannot only determine that attacks are occurring but in general terms who the source may be (Lee 2009).

Reduction of vulnerability is a practice that works equally well for both natural and man-made threats. Consider the following:

1. Build security and resilience into the design and operation of assets, systems, and networks. For a recent example, tank cars used for hauling crude oil underwent significant specification improvement that includes double-walled vessels and protection of related appurtenances because protecting infrastructure can also be a matter of improving the vehicles operating over transportation infrastructure (Edwards and Goodrich 2013).
2. Improving siting of infrastructure to avoid those areas prone to natural disasters or susceptible to exploitation. While this sounds obvious, its implementation may prove difficult especially with regard to maritime operations where access to deep water, both for channels and port facilities, is a prerequisite for attracting the services of, for example, container lines.
3. Develop and conduct training exercises to raise awareness and understanding of common vulnerabilities and potential mitigation approaches. Airport transit and passenger railroads have long engaged in such practices, and a common approach to mitigation is mutual aid agreements between first responders (Lee 2009).
4. Develop contingency plans for those events that have a higher likelihood of occurring. Railroads have long had agreements to use the tracks of competitors in the event of a disaster. This was seen numerous times when Gulf Coast hurricanes damaged stretches of track or bridges. Another example is the hurricane and tsunami evacuation routes posted in many coastal areas (McDougall and Radvanovsky 2008).

Notice that security and safety are, while related, different concerns. Moreover, resilience need to be considered together because as with the former, the focus is on prevention and protection, whereas with the latter, it is preparedness to mitigate, respond, and recover (Zoli and Steinberg 2016).

Step 5 demands that every event be assessed with regard to the effectiveness of those measures that were employed to prevent, protect, mitigate, respond, and recover from any event where transportation infrastructure was threatened, damaged, or destroyed. An after action report needs to assess what worked and what did not. This subsequently becomes the principal component of the feedback loop that serves to inform Step 1, the modification of goals and objectives, but also each of the other predecessor steps (NIPP 2013).

Conclusion

It must be emphasized that the orderly process for protecting transportation infrastructure must be an ongoing one because the environment is a dynamic one given the following considerations:

1. Infrastructure is always in the process of being replaced, upgraded, or generally maintained but also expanded to reflect increases in demand.

2. The demands placed on a particular element of the transportation infrastructure will change over time due to changes in economics including location of competing modes of transportation, location of those demanding transportation services, and the price of fuel and economics that may be related to such variables such as the price of fuel, taxation, and demographics.
3. Demand may shift due to the actions of government including taxation, weight and size regulations governing vehicles, and land use constraints.
4. The use may be affected by changes in the way costs are assessed, which could include the establishment of tolls, raising or existing tolls, or imposing time of day congestion pricing schemes.

Critical infrastructure · Drinking water · Wastewater · Interdependencies · Homeland security

Definition

Critical infrastructure is comprised of those systems and assets, whether physical or virtual, that are so essential to a nation that any interruption could have a severe impact on national security, public health or safety, economic well-being, or any combination thereof (GAO 2011). Water and wastewater critical infrastructure includes the infrastructure necessary to transport, treat, store, distribute, and remove drinking water and wastewater and also to control water quantity and quality (Alcaraz and Zeadally 2015).

Introduction

A nation's critical infrastructure, especially its water and wastewater treatment systems, provides the foundation for supporting public health, economic vitality, and healthy environment; defines its standard of living; and is the basis for a competitive advantage compared with other nations (Alcaraz and Zeadally 2015; EPA 2017; Jacobsen 2018). The reliability, performance, continuous operation, safety, maintenance, and protection of water and wastewater systems for producing clean and safe water must be a priority (Alcaraz and Zeadally 2015) as it is essential for sustaining life (Faily et al. 2015). The average person is only able to survive 3 days without water to maintain body systems health and functionality (Birkett 2017).

Highly sophisticated and intricate technology is required to run and operate our drinking water and wastewater systems (Birkett 2017). The US Water Critical Infrastructure Sector has historically provided clean and safe water to protect public health and the environment (EPA 2017). Guided by the requirements of the Safe Drinking Water Act (SDWA) and Clean Water Act (CWA), water utility service providers have been conducting routine daily, weekly, and monthly water quality monitoring for more than 30 years; as a result, the United States has one of the safest water supplies in the world (EPA 2017).

According to the US Environmental Protection Agency (EPA), approximately 153,000 public drinking water utilities and more than 16,000 wastewater utilities across the United States provide clean drinking water to almost 84 percent of the US population and wastewater treatment to more than 75 percent of the population (EPA 2017). Across the country, these systems comprise approximately 77,000 dams and reservoirs; thousands of miles of pipes, aqueducts, water distribution, and sewer lines; and 168,000 public drinking water facilities (many serving as few as 25 customers) (Clark et al. 2011a). There are 52,000 separate community drinking water systems in the United States (Finkel 2017).

Throughout history, even as early as 3000 BC, water critical infrastructure systems have been a consistent target. Increasing global populations in the twentieth and twenty-first centuries placed significant demands on water sources and water infrastructure resulting in water critical infrastructure becoming an increasingly attractive target for terrorist attack (Birkett 2017). There is growing awareness that urban water systems are vulnerable to both human-made and natural threats and disasters such as droughts, earthquakes, and terrorist attacks (Clark et al. 2011a). Earthquakes and terrorist attacks have many characteristics in common, because both are almost impossible to predict and can cause significant devastation and confusion (Clark et al. 2011a). This entry provides an overview of the water and wastewater critical infrastructure characteristics, followed by an explanation of the interdependencies of water systems and culminating in a discussion of the risks to water and wastewater critical infrastructure systems.

Water and Wastewater Critical Infrastructure Characteristics

Water supplies are typically from groundwater, surface water, or a combination of the two. Community water systems serving fewer than 10,000 people typically utilize groundwater, whereas large community water systems obtain the majority of their water from surface sources (EPA 2017). Conveyance systems bring water from remote sources to treatment plants using pipes or

canals. These conveyance systems can utilize pumping or gravity to move water from source to destination (EPA 2017). Raw water is commonly stored in remote reservoirs or lakes prior treatment (EPA 2017). Distribution systems, which include networks of pipes, tanks, pumps, and valves convey clean water to customers. Volume and pressure are controlled within the distribution system to ensure water is delivered when and where needed (EPA 2017).

Water treatment occurs via a variety of physical and chemical treatment processes dependent upon the contaminants detected in the raw water (EPA 2017). Initial treatment processes include coagulation, flocculation, and sedimentation followed by filtration. Surface water supplies are generally treated at conventional facilities using filtration to remove particulates and pathogenic microorganisms (Clark and Deininger 2000). The filtration process is followed by disinfection using chlorine dioxide, potassium permanganate, and nano-filtration (Clark and Deininger 2000). The disinfection process eliminates disease-causing organisms such as cysts or enteric viruses (Tech Brief 2006). Finished water is stored in a treated water storage area before distribution to customers. In a few cases, treated water is stored in large, uncovered reservoirs that may be susceptible to attack or contamination (EPA 2017).

Monitoring is conducted for common regulated and unregulated contaminants. Many community water systems install sensors at critical points to monitor physical properties, such as water pressure and water quality (EPA 2017). Integrated control systems which include supervisory control and data acquisition (SCADA) systems are essential to drinking water utility operation. These electronic networks are often dependent upon wireless communication which links treatment and distribution monitoring and control systems to a central display in the operation/control room (EPA 2017). Process systems and operational controls for operations of the utility and treatment processes are provided by electronic control systems not controlled by the utility's SCADA system (EPA 2017). Non-operational control systems or enterprise systems such as customer billing, email, and other personnel-related applications and tools are also essential to the operation of water and wastewater critical infrastructure (EPA 2017).

Collection systems, which are typically networks of pipes, conduits, tunnels, lift stations, and associated equipment, convey and pump wastewater from the source to the treatment plant. Community water services usually have three types of sewers: sanitary sewers, storm sewers, and combined sewers. Treatment plant operations can vary significantly depending on the type of collection system used (EPA 2017). Preliminary treatment can include removal of foreign materials that could damage a plant's infrastructure or impair treatment operations. Usual methods of removal include the use of chemical addition, pre-aeration, bar racks, screens, shredding equipment, or grit chambers. Pretreatment processes include coagulation, flocculation, and flotation to remove particles and solids (EPA 2017). Primary treatment removes suspended and floating material. Secondary treatment reduces dissolved and colloidal organic substances and suspended matter and is commonly accomplished through the use of settling tanks to separate liquid from solids.

Flotation and other methods are also frequently used. Grease, heavy metals, solids, and nutrient are removed through chemical processing. A combination of physical, chemical, and biological processes removes or reduces nutrient and soluble organic content (EPA 2017). Disinfection processes neutralize pathogens, bacteria, viruses, and protozoan cysts in the water disinfection processes. The most common disinfection processes are chemical disinfection (most often using chlorine), ozonation, and ultraviolet (EPA 2017). Effluent can be discharged to a body of water or wetlands and to groundwater aquifers via percolation or deep-well injection, applied on land, or re-repurposed (EPA 2017). The costliest part of wastewater treatment is the handling of residuals and biosolids. Solids treatment includes thickening, stabilization, digestion, chemical, composting, dewatering, incineration, and heat drying equipment (EPA 2017).

Monitoring systems are often installed at critical points to provide visibility on a range of

physical properties like flow rates and water quality indicators and to detect levels of contaminants throughout the treatment cycle (Clark et al. 2011a). One of the most common monitoring systems is the supervisory control and data acquisition (SCADA), which is a system of software and hardware elements including wireless communications and electronic networks that link monitoring and control systems for the collection, treatment, and discharge to a central display and operations room (EPA 2017). Process systems and operational controls which include electronic control systems related to the operations of the utility and treatment processes not controlled by the utility's SCADA systems (EPA 2017) are also used. Finally, nonoperational *enterprise control systems* including customer billing, email, and other personnel-related applications and tools (EPA 2017) also play an important role in the overall process.

Critical Infrastructure Sector Interdependencies

The material flows that constitute and sustain cities (water, electricity, gas, oil, food, information, and a multitude of other commodities) have traditionally been viewed and managed separately but are increasingly becoming interconnected and co-dependent (Williams et al. 2018). In sum, water critical infrastructure has become interlinked as communities have grown and developed. Today this critical infrastructure appears as intermingled distribution webs which meet the cyclic and intermittent growth of cities, towns, and communities (Birkett 2017).

The cascading effects of denial of water sector services would result in loss of other critical services, such as firefighting and health care, as well as adverse effects in other dependent and interdependent sectors, such as energy, transportation, and food and agriculture (EPA 2017). For illustration, the water and wastewater critical infrastructure systems sector is heavily dependent upon the chemical critical infrastructure sector to perform disinfection and water treatment. The chemicals are conveyed and delivered, by the transportation sector to water CI destinations, utilizing rail, road, and marine transport (Birkett 2017). The failure to understand how disruptions to one infrastructure sector could cascade to others, exacerbate response and recovery efforts, or result in common cause failures can leave planners, operators, and emergency response personnel unprepared to deal effectively with the impacts of such disruptions (Williams et al. 2018).

Most critical infrastructure sectors are, to a certain extent, dependent on the water and wastewater treatment sector. Porod et al. (2014) identify that most other critical infrastructure sectors are dependent upon water CI and would see degradations in service ranging from 67% to 99% after 4 h of water loss (Birkett 2017). Birkett determined 75% of all US critical infrastructure could be directly impacted should the continuous supply of treated water be lost. Community water supplies deliver water under pressure and are designed to supply most of the water for firefighting purposes. Loss of water or a substantial loss of pressure could disrupt firefighting, interrupt drinking water service, and undermine public confidence (Clark and Deininger 2000). The notion that our nation's critical infrastructures are highly interconnected and mutually dependent in complex ways, both physically and through a host of information and communication technologies (so-called cyber-based systems), is more than an abstract, theoretical concept (Rinaldi et al. 2001).

The water and wastewater sector is a lifeline sector with interdependencies to the 15 other critical infrastructure sectors. Because of the mutual dependence and interconnectedness made possible by modern information, communications, and cyberinfrastructure, our critical infrastructures are "system of systems" and are increasingly vulnerable in ways they have never been before (Gillette et al. 2002). Often spread over large geographic areas, these "systems of systems" can prove difficult to protect (Birkett 2017). Determining localized threat levels from deliberate adverse acts of human intervention or terrorism is also exceptionally difficult given the interconnectedness of the various critical infrastructure sectors (Birkett 2017).

The interdependent nature of critical urban infrastructure makes it more vulnerable to external impacts, leading to a domino effect among different assets and sectors impacting on people and places (Steele et al. 2017). Figure 1 illustrates the dependencies each of the other 15 critical infrastructure sectors have on the water and wastewater systems sector.

The manner in which the water and wastewater systems sector interacts with each of the other 15 critical infrastructure sectors is illustrated in Fig. 2.

Risks to Water and Wastewater Systems Sector

Due to the significant interdependency of the water sector with other critical infrastructure sectors, the vulnerability of a community's water critical infrastructure depends on the location and relationship of all the critical nodes comprising urban infrastructure systems, such as energy, food, water, sewage, and communications (Steele et al. 2017). Gleick (1993) commented that as civilization and development move forward in the twenty-first century, military action and instruments of war will increasingly involve water and wastewater, and water critical infrastructure will be an increasingly likely target of military or aggressive actions (Birkett 2017).

Historical examples of attacks and attempted attacks on water critical infrastructure are myriad. Terrorism is a significant threat to water security, and recent attention has turned to the potential that these attacks have for disrupting urban water supplies (Clark et al. 2011a). Terrorism in the United States was not considered a serious threat until the second half of the 1990s (Clark and Deininger 2000), but in recent times, Jihadist terrorist groups like Al Qaeda and others have shown an increased level of interest in attacks on water critical infrastructure (Birkett 2017). Recent attacks both at home and abroad have forced government planners to consider the possibility that critical elements of the US infrastructure might be vulnerable to terrorism (Clark and Deininger 2000). There were 162 documented attacks on water CI from 1980 to 2012, with a measured increase from 1970 (Birkett 2017).

Emergency response planning is inherent to the water sector because utilities have always had to respond to natural disasters. For decades, owner/operators of water sector assets have developed and improved plans to respond to human-made and natural disasters (EPA 2017). However, it was the threat of terrorism that prompted water, wastewater, and dam utilities to focus heavily on safety and security, for the protection of public health (Morley 2007). In particular, the 1995 terrorist acts in Oklahoma City and the September 11, 2001, attacks signified the need for changes in physical security of the water sector (Finkel 2017).

Aside from terrorism, security for water utilities is also concerned about two threats on the physical side: employee malfeasance from someone gone rogue and an outsider with a gun (Finkel 2017). The potential for chemical or biological contamination of water supply systems exists along with the possibility that such systems might be sabotaged (Clark and Deininger 2000). An employee with access could pollute the water, open a dam or valve when it should not be open, or power up turbines nefariously. There is a myriad of scenarios that could lead to a catastrophic event for that system (Finkel 2017). Figure 3 displays three levels of moderate, high, and significant risks to the water and wastewater treatment sector.

Numerous factors make water supply systems particularly vulnerable: they are spatially diverse; susceptible to intrusion; and component-rich (Clark and Deininger 2000). Water supply systems are generally governmental, with each supply system being highly localized (Clark and Deininger 2000). If wastewater infrastructure were to be damaged, the lack of redundancy in the sector might cause a denial of service. Disruption of a wastewater treatment utility or service can cause loss of life, economic impacts, and severe public health and environmental impacts. Regulations, research, and outreach, while extensive, have been aimed mostly at impacts on the environment and public health. Because drinking water is consumed directly, health effects

Sector	Sector Dependency on Drinking Water	Drinking Water Dependency on Sector	Sector Dependency on Wastewater	Wastewater Dependency on Sector
Chemical	• Manufacturing operations • Office operations	• Chlorine and other treatment chemicals • Office operations	• Manufacturing operations • Office operations	• Disinfectants and other critical treatment chemicals
Commercial Facilities	• Facility operations	• Bottling	• Facility operations	• Biosolids operations and distribution • Business operations
Communications	• Equipment cooling • Common rights-of-way	• Emergency communications with responders • General operations • SCADA • Monitoring	• Infrastructure access • General operations • Common rights-of way • Equipment cooling	• Common rights-of-way • Communications with emergency responders • General operations • SCADA • Remote monitoring • Communications with the public
Critical Manufacturing	• Water as a product constituent • Equipment cooling	• Operational and process equipment	• Manufacturing operations • Office operations	• Critical manufactured utility operations • Piping and infrastructure
Dams		• Storage; reservoirs • Flood mitigation	• Aquifer recharge	• Storage reservoirs • Flood mitigation
Defense Industrial Base	• Office operations • Equipment cooling	• Production of parts	• Office operations	• Production of parts
Emergency Services	• Continuity of operations • Firefighting and hazardous material spill and event responses • Decontamination services • Emergency water supplies • Equipment maintenance	• Special weapons and tactics and tactical operations • Coordination with the Incident Command System (ICS) • Law enforcement • Bomb explosive ordnance disposal • Emergency (medical and firefighting) responders • Hazardous materials (HAZMAT) responders	• Continuity of operations • Decontamination services • Infrastructure access	• Special weapons and tactics and tactical operations • Coordination with ICS • Law enforcement • Bomb explosive ordnance disposal • Emergency (medical and firefighting) responders • HAZMAT responders
Energy	• Cooling and scrubbing • Steam generation • Mining operations • Ore processing	• Process power • Pump, wells, treatment, operations • Office operations	• Waste management • Common rights-of-way • Methane generation • Cooling and scrubbing • Steam generation • Methane generation • Mining operations • Ore processing • Raw material (e.g., hydrogen production) • Refining	• Pumps and treatment; operations and repair • Office operations • Common rights-of-way • Repair and recovery operations • Process power • Delivery of components and material • Backup power requirements
Financial Services	• Office operations	• Facility financial operations, bonds, grants, loans, etc.	• Office operations	• Rates and spending authority • Research • Company operations

Critical Infrastructure: Water and Wastewater Systems Sector, Fig. 1 (continued)

Sector	Sector Dependency on Drinking Water	Drinking Water Dependency on Sector	Sector Dependency on Wastewater	Wastewater Dependency on Sector

Transportation Systems	• Office operations • Common rights-of-way	• Delivery of treatment chemicals • Operations, maintenance, and repair • Delivery of components and materials • Company operations • Transport of emergency responders and equipment • Common rights-of-way	• Office operations • Common rights-of-way	• Delivery of treatment chemicals • Operations, maintenance, and repair • Delivery of components and materials • Company operations • Transport of emergency responders and equipment • Common rights-of-way

Critical Infrastructure: Water and Wastewater Systems Sector, Fig. 1 Critical infrastructure sector interdependencies. (Adapted from 2015 water and wastewater sector-specific plan, US EPA 2017, Appendix 4, pages 40–42)

associated with contamination have long been major concerns. Besides, interruption or cessation of the drinking water supply can disrupt society, affecting human health and such critical activities as fire protection that can have significant consequences to the national or regional economies. The public correctly perceives drinking water as central to the life of an individual and of society. Consumers are highly sensitive to the threat of contamination or disruption (EPA 2017).

Although wastewater may not be an obvious critical security concern, there are clear environmental implications if poorly treated water would be pumped into waterways (Faily et al. 2015). There are more than 16,500 publicly owned treatment works (POTW) in the United States that

Sector	Water & Wastewater Systems Interaction
Chemical	EPA coordinates risks associated with the storage, transport, and use of chemicals in water utility operations. Water and Wastewater Sector owners and operators coordinate with federal, state, and local authorities to ensure compliance with chemical safety regulations.
Commercial Facilities	Water and wastewater utilities provide services necessary to the operations of commercial facilities.
Communications	Water and wastewater utilities must ensure communication between first responders during emergency management operations.
Critical Manufacturing	Water and wastewater utilities provide services necessary to the operations of manufacturing facilities, including a source of water for cooling or other processes.
Dams	Dams and reservoirs provide water for a significant fraction of the population. EPA coordinates with dam owners and operators including DOI that have responsibility for managing the Nation's dams and reservoirs, including pumping plants, canals, and pipelines.
Defense Industrial Base	Water and wastewater utilities provide services necessary to the operations of defense facilities.
Emergency Services	At the operational level, water utilities ensure that emergency responders have sufficient information to respond effectively to incidents at their facilities.
Energy	EPA also coordinates with the Federal Energy Regulatory Commission (FERC), which regulates interstate transmission of natural gas, oil, and electricity. EPA's interactions with FERC primarily involve the Water and Wastewater Sector's interdependency with electric power.
Financial Services	Water and wastewater utilities often utilize bonds, loans, and grants to fund operational changes and infrastructure upgrades.

Critical Infrastructure: Water and Wastewater Systems Sector, Fig. 2 (continued)

Sector	Water & Wastewater Systems Interaction
Food and Agriculture	With the issuance of HSPD-9, USDA expanded its role with the EPA to build upon and increase current monitoring and surveillance programs that provide early detection and awareness of the disease, pest, and poisonous agents.
Government Facilities and Commercial Facilities	Water and wastewater utilities provide services necessary to the operations of government facilities.
Healthcare and Public Health	With the issuance of HSPD-9, USDA expanded its role with the EPA to build upon and increase current monitoring and surveillance programs that provide early detection and awareness of the disease, pest, and poisonous agents. Water and wastewater utilities coordinate with public health agencies during emergency response and other water quality-related events, as well as provide services necessary for the operations of medical and other healthcare facilities.
Information Technology	DHS National Cybersecurity Division (NCSD) oversees the protection of the IT industry and also has a cross-sector responsibility regarding the security of industrial control systems that are critical for all sector operations.
Nuclear Reactors, Materials, and Waste	Water and wastewater utilities provide services necessary to the operations of nuclear facilities, including a source of cooling water.
Transportation Systems	The Water and Wastewater Sector shares several key interdependencies with DOT, including its reliance on the Transportation Systems Sector to provide chemicals, such as gaseous chlorine, and supplies for drinking water and wastewater treatment facilities. Highways and railways can also present vulnerabilities to the Water and Wastewater Sector where they pass near or over sources of drinking water.

Critical Infrastructure: Water and Wastewater Systems Sector, Fig. 2 Water and wastewater systems interaction with other CI sectors. (Source: Adapted from *2015 water and wastewater site-specific plan* (EPA 2017), Appendix 4, pages 42–44)

collectively provide wastewater service and treatment to more than 227 million people and are generally designed to treat domestic sewage (EPA 2017). Non-domestic industrial users also discharge effluent into collection systems for subsequent treatment at a POTW and are subject to the national pretreatment program (EPA 2017). According to Bahadur and Samuels (2011), damage to the nation's wastewater facilities or collection systems could result in loss of life; catastrophic environmental damage to rivers, lakes, and wetlands; and contamination of drinking water supplies (Clark et al. 2011a). Disruption of a wastewater treatment services can cause loss of life, economic impacts, and severe public health and environmental incidents. The lack of redundancy in the wastewater sector might cause a denial of service if wastewater infrastructure were to be damaged. The public is much less sensitive to the possible exploitation of wastewater infrastructure vulnerabilities compared to drinking water vulnerabilities (EPA 2017).

Most Significant Risks
• Natural disasters (such as impacts on water and quantity from floods, hurricanes, earthquakes, ice storms, pandemic flu, and other geographic catastrophes) • Economic implications of aging infrastructure • Cyber events • Capability in managing an area-wide loss of water Note: Although the Water Sector has been defined as a lifeline Sector, this is not commonly recognized among all relevant stakeholders, a situation that can escalate consequences during area-wide events.
High Risks
• Economic costs of preparing and response: The Water Sector can create a substantial economic risk in a disaster, but there are insufficient funds to prepare for and address risks ahead of time • Ignorance about the consequences of inaction and apathy from some stakeholders in utilities, the customer base, state/local government, and Federal Government/Congress • Inadequate coordination and information sharing during preparation, response, and recovery • Intentionally malicious acts • Limited resource availability: Many utilities for competing for needs (e.g., regulatory, aging infrastructure, environmental and public health protection, and workforce succession requirements) that are immediate, concrete and can limit resource availability for implementing preparedness and resiliency improvements • Unenforced and outdated requirements that do not address evolving threats.
Medium Risks
• Lack of mutual aid agreements, effective education, and outreach to emergency management, and lack of best practices for emergency response planning • Technology interoperability issues that create information-sharing challenges during the response • Insufficient communication to water utility boards of the definition, management, and prioritization of the critical assets and needs

Critical Infrastructure: Water and Wastewater Systems Sector, Fig. 3 Risks to the water and wastewater treatment sector. (Source: Adapted from the 2013 roadmap to a secure and resilient water and wastewater sector and 2015 water and wastewater sector-specific plan)

Conclusion

In the United States, society relies on the water and wastewater treatment systems to live, and this sector shares a significant interdependency with the other critical infrastructure sectors (EPA 2017; Jacobsen 2018). The vulnerability of a community's water critical infrastructure depends on the location and relationship of all the critical nodes comprising urban infrastructure systems, such as energy, food, water, sewage, and communications, and interruption would result in a cascading adverse effect (EPA 2017; Steele et al. 2017). There is growing awareness that urban water systems are vulnerable to both human-made and natural threats and disasters such as droughts, earthquakes, and terrorist attacks (Clark et al. 2011a). Moreover, increasing global populations in the twentieth and twenty-first centuries placed significant demands on water sources and water infrastructure, resulting in water critical infrastructure becoming an increasingly attractive target for terrorist attack (Birkett 2017).

Definition

In the United States

The term "critical infrastructure" has the meaning provided in section 1016(e) of the USA Patriot Act of 2001 (42 U.S.C. 5195c(e)), namely, systems and assets, whether physical or virtual, so vital to the United States that the incapacity or destruction of such systems and assets would have a debilitating impact on security, national economic security, national public health or safety, or any combination of those matters.

Presidential Policy Directive-21 (PPD-21, 2013)

PPD-21 defined critical infrastructure. The final piece of this subject is protection. Protection is "Those capabilities necessary to secure the homeland against acts of terrorism and manmade or natural disasters." (PPD-8, 2011)

Introduction

As defined above Critical Infrastructure Protection (CIP) of key infrastructures is essential to maintaining our way of life. The CIP programs must be of the highest priority of a government and its citizenry. The US government organizes the nation's critical infrastructure into 16 categories or sectors. Where the United States defines 16 sectors, the international community defines a global approach to a framework. The Center for Security Studies (CSS) published in 2009 the International Critical Infrastructure and Information Protection (CIIP) Handbook (CIIP 2009). This entry will focus on the US CIP Program. However, since the United States is a part of and is within the CIIP Handbook, the international framework will be discussed.

The international and the US approaches used the same baseline study initiated by the United States. The premise for both programs used the findings of the US President Commission on Critical Infrastructure Protection (PCCIP) of 1997. The PCCIP summarized two attack modes toward critical infrastructures. These modes are attacks against physical and cyber of essential targets to infrastructure (PCCIP 1997).

The US DHS is the focal point for CIP initiatives. However, the National Institute for Standards and Technology (NIST) is contributing to the nation cybersecurity governance. NIST established the National Cybersecurity Center of Excellence (NCCoE). As with the national CIP Program, NCCoE is a public-private partnership. This partnership provides cybersecurity solutions for an aspect of the US CIP Program.

The International CIIP Framework

The CIIP framework and program is the result of a research effort conducted by the Center for Security Studies (CSS) at ETH Zurich. The 2008/2009 International Handbook published the findings of this research. The CSS handbook investigated the critical infrastructure programs of 25 countries. Additionally, they analyzed the essential policies of infrastructures of the seven international organizations. This research used the US President's commission on critical infrastructure protection of 1997 (PCCIP 1997) as its basis. The PCCIP Report commissioned by President William Clinton appointed Robert T, Marsh as the commission's chairman. The commission report identified risks and vulnerabilities to infrastructures.

Additionally, the PCCIP report summarized the mode of attack to critical infrastructure targets in two domains. These attack domains are physical and information (Cyber). Therefore, the CSS found that information is a part of critical infrastructure protection and not a separate assertion. Thus, the term critical infrastructure and information protection (CIIP) is essential. As the CSS researched the 25 countries and reviewed the initiatives of 7 organizations, they emphasized the CIIP construct (CIIP 2009). The PCCIP Report identified targets as facilities, people, media, financial, computers, and information.

The research involved a review of 25 countries using 5 focus areas. The first area was to define how the surveyed country defined critical infrastructure. They then reviewed each country's policies and initiatives; CSS reviewed the country's organizational structure and evaluated

the country's public outreach and involvement; and finally, they assessed country's governance (CIIP 2009). By using these focus areas within their research approach, CSS normalized the comparative analysis of the surveyed country and the international approach to the protection of critical infrastructure.

The final step of the CSS research reviewed open-source material and collaborated with national experts from academia and government-related experts. This step utilized the knowledge, skills, and outreach of 7 internationally known organizations.

The US CIP Program Evolution

Like the international effort shown by the CIIP framework, the US program became formalized after the issuance of the PCCIP Report of 1997. In May 1998, President Clinton issued Presidential Decision Directive number-63 (PDD-63). PDD-63 established a national goal for the United States. This goal provided a framework for a public-private partnership to mitigate infrastructure vulnerabilities. To that end, the directive designated federal executive agencies to lead sector governance base on the agency's mission (PDD-63). The most significant action from the instruction was the establishment and the appointment of the national coordinator for security, infrastructure protection, and counter-Terrorism (PDD-63 1998, p. 11). In the ensuing years, the nation was working with the national coordinator to mitigate vulnerabilities to infrastructures. Following the events of the terrorist acts of September 11, 2001, the nation increased its efforts toward physical protections (CRS 2012 and 2015). As these protection efforts progressed, the US Congress became increasingly interested in the efforts that the nation was undertaking. The US Congress directed the Congressional Research Service (CRS) to research the activities surrounding critical infrastructure protection. John Moteff, a CRS specialist in science and technology policy, reviewed two historical products. CRS published the first in 2012. Its title is critical infrastructure resilience: The Evolution of Policy and Programs and Issues for Congress (CRS R42683 2012). Contained within this report was the definition and measurement of resilience. The report refers to resilience as ". . .the ability of a system to resist, absorb, recover from, or successfully adapt to a change in environment or conditions. . ." (CRS R42682 2012 summary page 1).

The 2012 report summarized the actions made under the Presidents Bush and Obama administrations. Upon the election of President Bush, his administration continued the initiatives started by the Clinton administration (CRS RL30153 2015). The National Security Council was reorganized into 17 policy coordinating committees (PCC) (CRS RL30153 2015). Eventually, the management and oversight for counter-terrorism and national preparedness, PCC was established within the executive office of the president (EOP). The next action the administration took was the establishment of the federal chief information officer (CIO) under the EOP deputy director of the office of management and budget. This position would serve in an oversight role of the federal agency's CIOs. During the same period, the Department of Defense chartered a commission on national security/21st century (USCNS/21) in 1998. This commission was also known as the Hart-Rudman Commission (or Taskforce). The Hart-Rudman Commission released its findings on January 31, 2001. The significance of these findings was that after the terrorist attack of September 11, 2001, President Bush established the Department of Homeland Security, as recommended by the report (CRS RL30153 2015).

The President Bush Administration issued high-level policy documents. They were the National Strategy for the Physical Protection of Critical Infrastructure and Key Resources (2002), Homeland Security Presidential Directive 7 (2003), and the National Infrastructure Protection Plan (NIPP) (2006). However, these documents did not adequately address resilience (CRS 2012).

Under the President Obama administration, resilience was integrated with the homeland security policy. In February 2010, the Quadrennial Homeland Security Review (QHSR) referenced

resiliency. The QHSR identified five core missions. These missions are:

> Mission 1: Preventing Terrorism and Enhancing Security
> Mission 2: Securing and Managing Our Borders
> Mission 3: Enforcing and Administering Our Immigration Laws
> Mission 4: Safeguarding and Securing Cyberspace
> Mission 5: Ensuring Resilience to Disasters (QHSR 2010, pp. 14–15; DHS Annual Report 2010)

With the addition of resiliency to the program, the subsequent NIPP publications strengthen not only preparedness but resiliency. Also, under the President Obama administration, DHS issued two revisions of the NIPP (2009 and 2013). Each revision prompted the development of CIP Sector plans. It was these efforts by the two formers presidents that formed the current US Critical Infrastructure Protection program.

The US Critical Infrastructure Protection Program

The US and the international CIIP programs formally started after the publication of the PCCIP Report of 1998. In the previous section of this entry, President Clinton issued PDD-63. PDD-63 outlined the infrastructures that require protection. These infrastructures are critical in that disruption; it would cause adverse consequences to the welfare of the United States (PDD-63 1998). In the wake of the terrorist attack on September 11, 2001, President Bush passed into law on October 26, 2001, the "Uniting and Strengthening America by Providing Appropriate Tools Required to Intercept and Obstruct Terrorism Act of 2001. The acronym USA Patriot Act is a shortened description of this act. In late 2006, the US Government General Accountability Office (GAO) found that most of the nation's critical infrastructure is owned and operated by a state, local, tribal, territorial (SLTT), and private organizations (GAO 07-39 2006). As such, this places a unique governance responsibility on the US federal government to provide informative governance to the critical infrastructure community. Contained within the 2006 NIPP, the following notation stated: "Private sector owners and operators are encouraged to participate in the NIPP partnership model and to initiate protective measures to augment existing plans for risk management, business continuity, and incident management and emergency response in line with the NIPP framework" (NIPP 2006, p. 9). Note, unless otherwise codified by statute, conformance with US federal governance is only encouraged.

In as much as the preponderance of critical infrastructure resides outside of the US federal government, the Federal Bureau of Investigation (FBI) established a program named InfraGard.

> InfraGard is a partnership between the Federal Bureau of Investigation (FBI) and members of the private sector for the protection of U.S. Critical Infrastructure. Through seamless collaboration, InfraGard connects owners and operators within the critical infrastructure to the FBI, to provide education, information sharing, networking, and workshops on emerging technologies and threats. InfraGard's membership includes business executives, entrepreneurs, lawyers, security personnel, military, and government officials, IT professionals, academia and state and local law enforcement—all dedicated to contributing industry-specific insight and advancing national security. (InfraGard 2018)

The InfraGard program establishes seamless interaction between the private sector, SLTT government entities, and the federal government. This interaction facilitates information sharing with the critical infrastructure 16 sectors. The FBI Office of the Private Sector oversees the InfraGard program.

To review the evolution of the US National Infrastructure Protection Plan (NIPP) Sector program, a review of the issued NIPP documents will show the history. The first NIPP issued in 2006 identified 17 sectors aligned with Homeland Security Presidential Directive 7 (HSPD-7) (NIPP 2006). The next NIPP released in 2009 identified 18 sectors aligned with HSPD-7 (NIPP 2009).

In 2013 Executive Order (EO) 13636 of 2013, titled Improving Critical Infrastructure Cybersecurity, issued and directed (in-part) the executive branch of government to strengthen cybersecurity

practices and share cyber threat information (EO 13636). The US Presidential Policy Directive 21 (PPD-21) established the 16 critical infrastructure sectors and aligned them with a federal government agency. These agencies referred to as sector-specific agencies (SSA). The current NIPP issued in 2013 identifies 16 sectors aligned with PPD-21. The 16 sectors are Chemical; Commercial Facilities; Communications; Critical Manufacturing; Dams; Defense Industrial Base; Emergency Services; Energy; Financial Services; Food and Agriculture; Government Facilities; Healthcare and Public Health; Information Technology; Nuclear Reactors, Materials, and Waste; Transportation Systems; and Water and Wastewater Systems (NIPP 2013).

According to the Cybersecurity and Infrastructure Security Agency (CISA) of the DHS website, the challenge program leverages the innovative research programs from DHS Science and Technology initiatives. Over the years 2016, 2017, and 2018, the challenge program has resulted in innovative recommendations from the public sector to advance CIP from a technological perspective (source: https://www.dhs.gov/cisa/nipp-security-and-resilience-challenge#wcm-survey-target-id).

CISA partnered with the National Institute for Hometown Security (NIHS). The below quote will show the purpose of this relationship.

> NIHS provides an opportunity for the critical infrastructure community to help develop technology, tools, processes, and methods that address immediate needs and strengthen the long-term security and resilience of critical infrastructure. https://www.thenihs.org/

Through this relationship and the challenge program, CISA provides the critical infrastructure community innovative research and solutions.

The National Cybersecurity Center of Excellence

As the nation becomes increasingly reliant on our cyber infrastructures, the National Institute of Standards and Technology (NIST) established the National Cybersecurity Center of Excellence (NCCoE). According to the NCCoE website, the goals of NCCoE are "...to provide practical cybersecurity, to Increase the rate of adoption, and to accelerate effective innovation..." (source: https://www.nccoe.nist.gov/about-the-center/strategy).

According to the NCCoE website, currently, eight projects relate to CIP sectors. These projects are consumer/retail, energy, financial services, healthcare, hospitality, public safety/first responder, transportation, and manufacturing. NCCoE refers to these projects as "use cases" (source: https://www.nccoe.nist.gov/projects/use-cases).

With the NIST involvement through the NCCoE will provide to the critical infrastructure community a directed approach to cybersecurity.

Conclusion

Since the early beginnings of characterizing certain infrastructures as critical, countries of the world are working toward making our planet a safer place to exist. Through the CIP and CIIP programs are providing the framework for this protection. The citizens of the industrialized world depend on multiple infrastructures to assure sustainment of their welfare. The total population has had and will continue to have an essential role in providing security to the facilities of these infrastructures. In the United States, the government has provided and continues to provide a framework for the nation to view and interact with infrastructures that are critical to the survivability of the country. The nexus shown between the US DHS, NIST, and CSS provide a different view of the CIP environment. This entry has provided a synthesis of the founding of CIP, internationally, as well as the approaches to analyze and implement infrastructure protection.

Definition

Cultural property protection involves the complex and far-reaching issues securing a wide range of institutions. This entry primarily deals with museums; however, the concepts and considerations can be extended to the types of institutions which have numerous references, legal, and industry standards.

Introduction

Cultural property protection is a vast topic that includes an array of variables to consider. They face the same threats as every other public institution with the added complexity of protecting collection items while making them accessible to a wide range of visitors from school children to researchers. The items that need protection may be the property itself, irreplaceable art or artifacts, living animals or plants, and in some cases items in open public spaces. Events in the early part of the twenty-first century have resulted in a rise in violent attacks on artwork and at cultural properties of all types along with the overall increases in crimes including loss of human life. The value of art, insurance, and liability issues have necessitated a more serious focus on security in cultural properties. An incident of any kind can affect an institution's reputation with the public, groups, or other professional organizations. These may impact attendance; the ability to get loans, funding, or grants; increases in insurance premiums; and the ability to secure loans.

Types of institutions are:

1. Museums
2. Libraries
3. Aquariums
4. Botanical gardens and arboretums
5. Historical sites
6. Monuments

Personnel and Hiring of Security Force

The responsibility of any Security Director is to staff the security team with competent and able individuals. This task starts with the hiring process. The first step in that process is to post the position on any of the various job websites that provide suitable candidates for any position. The resumes must be read and analyzed to find the right candidates for the position. Suitable applicants are then scheduled for interviews. The number of resumes is then parred down to a manageable number; thus, interviewer starts the interview process. The interviewer must begin by stating the requirements of the position. It is important to point out the need to be available to work weekends, holidays, evenings, and nights. If the candidate is not willing or able to meet the basic requirements of the position, the interview should be terminated.

Once the basic requirements are met, the in-depth part of the interview begins. The questions poised must be able to draw out the personality of the candidate without being too intrusive. Questions should include the candidate's experience, the history of employment, gaps in the employment list, etc. In addition, the candidate must be articulate, well-mannered, and present a professional

appearance. The interviewer should review all pertinent documents such as DMV license (if required), address verification, security license, employment authorization card (EAD) or green card, military discharge papers (dd214),testimonial letters, passport, and training certificates. During this process it must be established that the applicant is legally able to work in the United States. The interviewer must ascertain if the candidate has the ability to act independently when necessary based on the policies and procedures of the institution.

Once the candidate is chosen, the Human Resource Department must perform a background check to include criminal, financial, education, and employment. The candidate must present three references which must be verified.

When background and references are confirmed and found to be acceptable, the Security Director or Manager must ensure that the candidate's licenses and permits are valid and up-to-date. Once the process is satisfactorily completed, the candidate will be notified with an offer of employment and a starting date confirmed.

Guard Staffing, Training, and Deployment

Perhaps, the most overlooked and underappreciated aspect of cultural property protection is the uniformed security officer or guard. The human element is essential to any modern well-run and efficient security program. A well-trained officer can prevent almost any damage, theft, or problem that may arise on a cultural property floor. It is entirely up to the institution as to whether the officers are armed or unarmed. If they are armed, the institution must ensure that they are licensed and nave completed any required training deemed necessary by the licensing agency.

The guards must be well dressed in uniforms that ensure the public has the ability to see them in a crowded gallery or area. The uniforms should consist of a jacket, slacks, white shirt, tie, and black shoes. A patch of insignia of the institution is usually located on the pocket of the jacket or the sleeve. The uniforms should point out the authority of the guard while not being too militaristic. If the guard has outdoor post duties, the appropriate gears such as parka with insignia, jacket, and rain gear must be issued, as well as necessary equipment including flashlights, electronic post-monitoring equipment, and hats.

Training

Once the candidate is hired, the training regimen is commenced. In most states, each security guard must be licensed. The training for the license consists of an 8-h pre-employment training and a 16-h post-employment training. Additional, annual 8-h training is required in order to maintain the guard's license. Each institute must conduct training sessions tailored to the specific site. The guard must be trained on fire safety, including location of fire exits, exits in the building, location and type of fire extinguishers, emergency and evacuation procedures, customer service training, and conflict resolution. Additional training by reputable professionals should be included to inspire, educate, and motivate security personnel. An in-depth insight at fire, emergency, and customer service training is covered later in the chapter (Nemeth 2018).

The guards should be well informed regarding the collection they are protecting. The presence of guards not only protects the collection, but they are fine representative of the cultural institution. In almost every museum, the security guard is the first and last member of the museum staff that is visible to the visitors. The modern-day museum guard must possess the necessary skills to handle diplomatically school children visitors on a class trip, the high-end donors, and everyone in between. In order to obtain these skills, the uniformed guard must be trained. This training is not universal in its approach. Each museum, library, and other cultural institution is unique unto itself, and thereby, the training must be specific to the building or site to which they are assigned. Additional information regarding training can be found later in the chapter.

Staffing

The Security Director or Manager has two options when hiring security guards. The choices are to hire propriety guards or contract ("rent") guards, both having its advantages and disadvantages.

The propriety guard is hired by the institution. There three advantages of employing guards in this manner rather than renting them through a third party. First the guards are trained by the security management staff at the institution, allowing them to become well versed and knowledgeable in the operation and use of the building in which they working in. Second they will develop a sense of loyalty to the institution and feel as though they are an integral part of the staff. Third propriety guards have the advantage of generous compensation packages including annual vacation, sick time, healthcare coverage, retirement plans, and sometimes even tuition reimbursement.

There are three disadvantages to hiring propriety guard. First the cost of employing a propriety staff is much more than a contract company. Second the administrative challenges are many, sick time, vacation time, and disciplinary matters. Third some guards are governed by union contracts that are negotiated and must be adhered to. All of these are a burden on the hiring institution.

In contrast, the advantages of contracting with a company is that it is generally less expensive to the institution as the agreed upon price is paid and all other costs (e.g., equipment, uniforms, compensations packages) are absorbed by the contract company. The contract company deals directly with the union both contract and any other problem. The advantage of a contract company is that the hiring institution does not have to abide by formal disciplinary procedures to deal with unsatisfactory performance. The contract guard benefit package is generally less costly to the hiring institution. Another disadvantage is that contract guards have no loyalty or commitment to the institution that they are assigned. This can create a lackluster performance. They are generally less trained and, for the most part, not well versed in security practices and procedures. If a contract firm is used, the hiring company must check that the contract companies' certificate of insurance is up to date and a copy must be maintained by the Security Director. In addition the hiring company must establish what equipment the contract company is responsible for, i.e., flashlights, uniforms, radios, etc. The contract firm must provide and keep an updated list of the guard's licenses and other pertinent information.

Many museums employ the hybrid system. They hire a staff of propriety guards and supplement them with contract guards. This has a different set of advantages and disadvantages. The favoring factors are that the number of contract guards can vary according to the needs of the institution. For example, a museum has a popular exhibition without a sufficient number of propriety guards to protect the exhibition. The museum hires contract guards to fill the void for the duration of the exhibition. When the exhibition ends, the contract guards are dismissed. This is a cost savings to the museum. The disadvantage is that contract guards are compensated less than propriety guards and are performing the same functions. This leads to conflicts between the guards and can cause personal problems among the guards, thus causing substandard protection of the collection and the visitors.

Guard Deployment

The standard policy for almost every museum is to have a guard within eyesight of each piece of art or display.

Some institutions have adopted the roaming guard policy. This policy dictates that guards roam from one gallery to another, thereby leaving art pieces unprotected and open to theft, damage, or other problems. The roaming guard concept is a result of money-saving attempts by the institution. Another money-saving attempt is to hire gallery attendants to replace security guards. These attendants are not routinely trained in fire safety, emergency methods, and first aid practices; they are generally less observant.

These cost-saving measure places the collection, visitors, and staff in jeopardy. The risk is too high to consider. It takes just one individual with nefarious intentions to not only ruin a priceless piece of art but also damage the reputation of the museum or cultural institution.

Physical Security

The Security Director or Manager is tasked with the responsibility of protecting the priceless

pieces of art, artifacts, antiquities, books, manuscripts, and sometimes living assets. This is predominantly performed by the guard staff and assisted by the use of physical exterior and interior security. Exterior security includes, but not limited to, fencing, camera (night vision) bollards, gates, and barriers. Interior security includes, but is not limited to, doors, locks, stanchions, cameras, motion detectors, access control, and glazing, to name a few. Each of the aforementioned should be utilized on a site-specific manner.

Exterior: The area directly in front of the building or site that is being protected should be clear of any obstructions. Shrubs, trees, debris, etc. should be cleared away from any door, gate, or other entrance. Parking lots should not be directly adjacent to the building or site. Parking lots should be a safe distance from the building in order to provide adequate security.

Perimeter lighting is an essential element to any physical security plan. Based on the type of institution, the lighting should be tailored to produce sufficient lighting to protect the area from intrusion and also provide a sense of security and safety to staff and visitors. There are minimum standards for lighting various spaces. *See* the Illuminating Engineering Society of North America, Guidelines for People, Property and Public Space. There are several types of lighting that are used for certain applications. They are as follows:

- Incandescent (generally used in home or offices this type is being phased out by the government)
- Mercury vapor lamps
- Metal halide
- Sodium vapor lights
- Quartz lamps
- LED
- Electroluminescent
- Halogen

Fencing

Zoos or wildlife parks are one such venue that require exterior fencing. The use of fencing, moats, and glass enclosures protect the public from animals, insects, birds, reptiles, and them from the public. When installing chain-link fencing for spaces other than zoos or wildlife refuges, the fencing should meet the US Department of Defense specifications. *See* their website for more information. When installing fencing or enclosures for zoos or wildlife refuges, see the Zoological Association of America Standards 2016. For the safety of the animals, staff, and visitors within the museum arena, the use of stanchions is more prevalent than other cultural properties. Well-placed stanchions act as barriers to protect art work. However, many museums curators frown upon their use believing they detract from the public's ability to properly view and enjoy the art. This is a continuing dilemma for the security professional and the museum's curatorial staff. Another method of protection is the use of sandpaper tape. This tape is placed on the floor in front of the art work. It can easily be stepped over, but it acts as a deterrent to keep the public at arms distance away.

Glazing

Many pieces of art are protected by glazing. Glazing is the process of placing a piece of museum glass over and existing piece of art. This glazing not only protects the art from the intentional or unintentional touching from the public, it also protects the art from harmful UV sunlight rays that may damage the art. Again, some artists refuse to allow this process adding an extra burden to the security professional.

Doors and Locks

Doors and locks are the most common and one of the best methods of protecting priceless works. The use of doors should be limited to protecting areas of the museum that are not accessible to the general public. Each of these entranceways should be equipped with electronic means of operation, i.e., card access (electronic access will be discussed later in the chapter) allows the security staff to limit access to areas and the ability to monitor said space to record who entered and what time the space was entered. If the institution uses a traditional lock system (key), the security department must maintain an up-to-date key register. Keys should never be issued unless they are approved by the department head and authorized by the Security Director.

Bollards and Barriers

Stone planters decorated with colorful flowers, shrubs, etc. line front of buildings. These planters or bollards serve a dual purpose. First they protect the area from any attempt to drive a vehicle through the front, side, or rear of the building. They are an effective method of stopping a terrorist from carrying out their attacks, plowing into the building with a bomb. Second, they add a sense of beauty to the area. There should also be intrusion-protective devices, drum-type barriers, retractable barriers, and sliding gates used at entrances to parking areas to prevent vehicles from entering secure areas (Nemeth 2018).

The Security Director along with the Facilities Manager must be aware of the potential threat of someone attempting to sabotage the building's HVAC systems. Precautions must be taken to protect all vents, access pipes, and other building access ports.

Cameras, access control, motion detectors, glass protection, as well as any other electronic security devices will be covered later in the chapter.

Alarms and Electronic Systems

Intrusion, Perimeter, and Specialty Alarms

The use of electronic alarms and surveillance has become an integral part of cultural property security and has greatly expanded the ability to monitor items or spaces with degrees of accuracy well beyond what can be accomplished by staff alone. Ideally, there would be multiple independent systems in place with overlapping coverage (in case of the event that one is compromised, intentionally or accidentally). The system should be self-monitoring and programmed to issue a warning if there is a breach or failure. It should also be supervised on-site and through an off-site central station with contact to local law enforcement, fire service, museum management, and any other preselected contacts in the event of an emergency.

Video Surveillance

Technological advancements have greatly expanded the use of video systems to monitor a space or object, serve as a deterrent, or aid in investigating an incident. Through the use of intelligent video technology, cameras can be used effectively to isolate spaces and monitor conditions, license plates, faces, persons, etc. This is especially important when critical or large areas need to be covered. Integrating alarm and access control systems with the video system can also be used to verify staff locations and record detailed activities, criminal, or otherwise.

States of Operation

A sound foundation of cultural property protection (CPP) requires a complete knowledge of the institution, personnel, structures, and grounds along with a properly trained staff as well as having the necessary policies, procedures, and systems in place. Understanding the various states of operation is essential to anticipating and preparing for the inherent risks CP face. Some circumstances may require additional or specialized staff, inspections, procedures, and the notification of outside agencies (i.e., fire service, insurance carriers, etc.).

The first four normal states of operation present well-understood risks which are handled with policies and procedures specific to the institution (Liston 1993). The last two special states present a number of risks which must be identified in advance. In all cases, emergency plans must be developed and practiced in advance since they can occur in any state.

The six states of operation are as follows.

State 1: Open to Staff and Public

This state is an institution's normal operating business hours. During this state of operation, both public visitors and everyday staff – office, shop, concessions, etc. – may be present.

State 2: Open to Staff, Closed to Public

This state covers any time staff members are expected to be at the institution, but the institution is not open to the public.

State 3: Closed to Staff, Open to Public

This state is when the institution is open to the public, but most of the staff is not present. This

state primarily covers public hours when office or back of house staffs are not present.

State 4: Closed to Staff and Public

This state is when the institution is closed to everyone. The only people in the building should be museum facilities and security staff as well as any other personnel essential to the operation of the facility and may include researchers or persons working on special projects.

There are, however, two special states that present additional risks and need to be considered.

State 5: Special Events

Basic special events such as tours, lectures, group visits, or meetings that occur during normal business hours are usually well handled with simply providing additional security to that event (if necessary). Larger and more complex events or those that extend into back of house spaces or take place after hours require coordination with internal and external parties. They sometimes expose the institution to potential problems, for example, outside personnel access to ordinarily restricted spaces, deliveries, storage of items, and removal of materials, equipment, or debris. Preparation, consumption of food, alcohol, and generally dealing with guests on site that may be there for purposes other than viewing the collection may present issues in terms of behavior or expectations. Special events also may include photo or film shoots, which may present risks inherent with having equipment or persons in close proximity to collections. Making sure all special events are separated from visitors (if possible) and do not disrupt the visitor experience be should be anticipated. Most events require coordination between departments, such as public relations, operations, exhibition design, visitor services, conservation, and, of course, security.

State 6: Construction Projects

Construction projects within the institution or with adjacent structures present a host of situations that may put the structure, collection visitors, or staff in jeopardy. Access for workers and material, in addition to the inherent risks of construction operations, require careful coordination with all internal and external stakeholders. While each project is unique, the security department is usually tasked with monitoring several key activities. Protection of the staff, guests, institution, and collections is the overall responsibility of the security department. Access control, fire system operation, life safety alarm systems, as well as threat of and response to emergencies are among the primary responsibilities of the security department. Proper planning should include modifications to standing policies and procedures which address the special additional concerns. These adjustments should address access issues, changes to normal operating procedures, and emergency response. This may require additional or specialized staff and training. They should include a site safety plan, trained construction safety personnel, and fire guards. Regular staff should also receive specialized training if they would need to access spaces as part of their regular work or in emergency situations. During the state of construction projects, the security department will work closely with construction managers, facilities, conservation, exhibition design, and any other departments involved with the project.

Protection of Collections

Exhibition

Security's place in the protection of the collection is varied in that they must protect the collection or borrowed work and still allow the visitors to view and enjoy the art. Additionally, security is responsible for the protection of the cultural institution's collection when it is not on exhibit.

There are certain fundamental precautions and procedures that must be instituted by the security department to deter or prevent anyone from causing damages intentional or unintentional to the collection on exhibit. The use of guards, stanchions, sandpaper tape, vitrines, tethering to the wall, museum wax, and glazing is some of the

traditional methods of protection an exhibition. For more information, refer to the American Museum Association. The use of cameras, motion detectors, and RFID tags (radio-frequency ID tags) is employed by many institutions to protect the collection.

Security must be knowledgeable as to the number and demographic makeup of the visitors. Is the exhibition appealing to a younger visitor – teen and/or child? If so, there are procedures that must be followed. Are strollers or baby carriages allowed on the exhibition floor? Are the children permitted to roam about unattended? For elderly or physically challenged visitors, are there wheelchairs, etc.? If a particular exhibition is popular, there should be a limit as to the number of visitors permitted in a gallery to avoid art damage and avoid emergency evacuation problems. School tours are a vital component of most museums. Guards must be assigned to every school tour that visits the museum. The uniformed guards must be well informed as to the value of each piece of art. They must give special attention to said pieces.

When an exhibition is borrowed (most museums lend and borrow art exhibits), the Security Director, in coordination with the Registrars, is committed to the borrowing policies set forth by the lending institution. Policies may call for a particular piece of art to be assigned to a dedicated guard during business hours and also during special events or tours that may take place. In addition, they may require special alarms, cameras, or RFID tags. If the piece is moved, an alarm is sounded and security is alerted. Some borrowing requirements are so stringent that they require that everyone be searched prior to entering the gallery.

Storage of the collection is another proponent of the protection of the collection. Every museum acquires art by purchase or from donations. These priceless pieces when not on exhibition must be stored. The storage facility must be temperature and humidity controlled, protected from fire, flood, theft, and any other disaster, natural or man-made. The storage site must be unobtrusive in nature, i.e., no signage indicating what the site is. The site must have state-of-the-art intrusion protection, early warning fire and smoke detection, and sprinkler systems that extinguish a fire and, at the same time, prevent any extensive water damage to the collection.

Admittance to the site must be limited only to the employees. The employees must be vetted and complete a background check. This must include a criminal, financial, and character investigation. When the facility is closed, no one should be permitted entry unless previously approved by the Head of the Curatorial Department after consulting with the Security Director.

Protection of Collections: Off-Site, In Transit, and Loans

Protecting collection pieces when not in the primary facility is complex since the control of the location and resources are harder to manage and maintain. Standard Facilities Reports used to record and verify a wide range of information about the institution, it's physical structure, security, fire, climate control, provisions for handling and packing, insurance, previous temporary exhibitions, and loans. In order to provide the same level of care there must be a full understanding of possible risks and vulnerabilities. Then planning and providing manpower and physical and electronic security, all other logistical considerations to accomplish the task must be implemented. In some cases, the collection pieces are exterior monuments or exist on extensive grounds or in parks. In other cases, the off-site location may be a storage facility, a research laboratory, or archeological site. The security plan should be developed, along with the subject matter experts, taking into consideration laws and customs, and with the cooperation of local governmental and emergency response providers. In all cases, financial planning is an essential part of the plan.

Collection sites are any location, active or inactive, where specimens, artifacts, or remains are collected. They may include archeological, underwater, previous civilization, or burial sites. Legal issues involve access permits, protests, as well as poachers, criminal activity, and vandalism. Collection sites on public roads, parks, and city streets require special plans to separate and protect both assets and the public from related activities. Specialized training, licenses or staff may be required;

each should be considered and planned well in advance. Transportation, communications, living accommodations, and medical care also need to be provided depending on site location. Emergency response and evacuation plans especially for remote or difficult locations must be completed and exercised.

In-transit protection of collection pieces, artwork antiques, documents, animals, plants, etc. is of great concern due to the additional risks presented while traveling. Factors to consider while preparing a risk analysis are value, vulnerability, distance, insurance requirements, and legal issues. The means and methods of transportation, requirements for care, environmental considerations, and packing are established by subject matter experts. The security arrangements are made along with the security management team after considering insurance, legal, and jurisdictional requirements. Care should be exercised in making travel arrangements in addition, accommodations for protection of items being transported, and overnight security, if necessary. Provisions may include armed or unarmed security escorts, climatized storage facilities, and emergency response while in transit. Maintaining communication with staff assigned to monitor movement and having continuous GPS tracking is common providing real-time tracking of personnel, vehicles, and cargo. Emergency and contingency planning should also be included.

Borrowed art, collections, objects, specimens, etc. are a primary concern for security and may require additional protection planning delineated in the loan agreement. These will be considered while preparing the lender's loan agreement and outlining, among other things, security and insurance requirements. They may also cover transportation requirements, escorts, documents, and import/export custom-related issues, which are usually coordinated through exhibition management staff along with security management. Exhibition designs that require the removal of existing collections, and the insertion of new ones, present a number of logistical and security-related issues, considering that the objects or specimens are most vulnerable to damage or theft while being handled, packed, or transported. Access and credentials for movers, couriers, and staff to restricted areas must be strictly controlled.

Construction

Security management must consider short- and long-term considerations from design considerations, through construction and commissioning, and into operation. All of these issues affect the construction costs and, as importantly, the operating costs. Local or national codes and regulations dictate the bare minimum required for occupancy, access, evacuation, fire, and life safety; however, they do not address the specific needs of cultural institutions. A comprehensive security survey must be prepared to determine project requirements. The survey should include access, guard placement, technology, and operating costs. By including security management and consultants who are experts in the cultural property protection field, changes, or even more costly retrofits, can be avoided. In addition, peer reviews are another frequently used method to ensure that the project is considering the myriad of threats and issues inherent in construction projects. The issue of construction on adjacent properties must also be carefully considered since they can affect site access and present a long list of hazards to staff, guests, collections, and the institution itself. In the case of any construction or renovation project, special security provisions should be made for day-to-day operations as well as emergency scenarios.

Security involvement in internal and external renovation or construction projects is well beyond the realm of ordinary access issues. Security management must be involved in every phase of the project.

Environmental Considerations

Environmental monitoring and control are most often handled by facilities and the exhibition staff with the advice of the conservation staff within well- documented criteria, i.e., custom details for the specific pieces. American Society of Heating, Refrigeration and Air- Conditioning Engineers

(ASHRAE) Applications 2015 includes a section on Museums, Galleries, Archives, and Libraries. The most fundamental environmental conditions are temperature and humidity. While not always critical to the collection, extremes conditions can present problems for guards and staff potentially affecting their performance, health, and well-being. Awareness of and possible exposure to gasses or chemicals used in laboratories, conservation, shops, or other day-to-day operations that security officers may encounter should also be considered. Carbon monoxide and combustible gas sensors should be incorporated in areas where these may be present. Security officers working alone, or in contained spaces, such as guard booths or patrol vehicles, should be further trained as to risks, detection, and prevention. Security staff should be trained on other environmental factors which could be hazardous to themselves, other people, and the collection, which may include animals, plants, etc.

In some cases, security personnel may be involved in completing environmental checks since they can easily be incorporated to normal rounds and inspections. Security should be trained as to how to identify and report environmental abnormalities. This should include water leaks, odors, or any other situations which differ from the norm. Training must include how to deal with exposure to harmful materials they may encounter while doing their normal work. In the event of an emergency, training should be in adherence to regulatory agencies and good industry practices and proper notifications, such as staff, emergency, and hazmat responders.

Fire, Life Safety, Emergency Planning Business Continuity

Fire

Museums are vulnerable to fire and the threat of fire then most other cultural institutions. Museums, libraries, house and exhibit books, and art works by their very nature are ignition sources for fire. Every institution must have in place a viable and up-to-date fire safety plan. The fire safety plan must be written and updated regularly. Changes in exhibitions will cause different paths of egress within gallery spaces. Roles must be defined and updated on a continuous basis. The fire plan must include every department and staff member. Fire prevention is everyone's duty and responsibility.

Fire plans must include a trained hierarchy of to respond to alarm and fire conditions and may include designated personnel such as an incident commander, wardens, searchers, and a fire brigade if appropriate. A comprehensive fire prevention plan must be developed and rigorously followed. The plan should include daily, weekly, monthly, and annual inspections to assure that the entire property is free from hazards and that all equipment and systems are fully tested and operational. Fire drills and training for all personnel is essential.

Sprinkler systems in various configurations are the most common type of fire suppression systems used in cultural institutions and include sprinklers, pre-action, and mist and in some locations deluge systems. Selection of the appropriate system must take into consideration what is being protected and the risk of collateral damage. Special extinguishing agents may be needed especially in laboratories, conservation, food preparation areas, or where high value or irreplaceable items are stored or exhibited. In some cases, low-oxygen environments or other specially designed environments should be utilized. Conversely, some locations may not require any suppression system at all but should still be considered and agreed to by all institutional partners and confirmed with local authorities and insurance company.

Fire Alarm Systems

Fire alarm systems are necessary in most CP environments and must be maintained and monitored continuously. An on-site fire alarm panel is used to monitor and collect information, annunciate alarms, communicate with off-site central station, and activate the fire suppression system. Fire alarm systems are usually mandated by local jurisdiction and often referred to standards, such as NFPA 909: Code for the Protection of Cultural Resource Properties and NFPA 914: Fire Protection of Historic Structures. The selection and placement of manual and automatic devices should be designed based on

the specific conditions and circumstances of the institution. Design, coordination, and integration should be done with the involvement of consultants who specialize in the field and are familiar with current codes, practices, technologies, regulations, and industry-specific standards.

Emergency Planning and Business Continuity

Emergency planning should be approached after careful consideration of risk analysis to the organization, collection staff, or guests. This is essential of preparing the overall protection plan and the emergency plan. It must be done in collaboration with the collection executive staff, conservation, and finance facilities and include the needs of all constituents. It is advisable to engage local emergency responders to familiarize them with special requirements, access, and equipment. Notification of staff and outside vendors via pre-established, procedures should be in place so that communication can be expedited. In addition, a prioritized list should be made for the relocation or in situ protection of property, artifacts, and records. Supplies of equipment and materials should be stored off-site, and arrangements for additional supplies should be planned. It is also advisable to have storage facilities and reciprocal arrangements with nearby cultural properties in the event of an emergency. The plan must be agreed to, adopted, implemented, and practiced on an on-going basis. Emergency procedures and the disaster recovery plans should cover all foreseeable disasters and emergencies.

Life Safety

The cultural property must be prepared for any type of emergency, whether it is man-made or a natural occurrence. The institution must have an emergency action plan (EAP). This plan should address any emergency other than fire which is covered in the aforementioned fire safety plan. Prior to writing an EAP, a vulnerability study should be conducted to ascertain the vulnerabilities that may affect the institution. When this study is completed, an EAP tailored to the needs of the institution can be created. The EAP should include provisions for evacuation of the site, sheltering in place, active shooter procedures, saving the collection and other valuables, alerting emergency responders, and the handling of the media. In addition to the EAP, there must be procedures for handling medical emergencies. The security staff should also be trained in first aid, CRP, and the use of AEDs (automated external defibrillators). Every emergency or fire plan requires testing, constant updating, involvement from all staff, drills, and after incident reviews to ensure that the safety and well-being of the institution is preserved.

Law and Legal Issues

Similar to the overall topic of cultural property protection, cultural property law must address all of the issues faced by other organizations with the added complexity of dealing with collection specific issues ranging from vandalism to animal rights. The primary legal issues that involve the security department are those that relate to guard actions concerning authority and responsibilities of security officers. Whether armed or unarmed, the local or national laws that outline guard actions, investigations, apprehension, detention, arrest, or use of force must be incorporated in the development of policies and procedures. In addition, security management must be aware of civil law that may affect the guard force and performing tasks such as assisting in medical situations, completing incident reports or occupational health issues. Labor law is another area often referenced due to the wide range of situations that security departments deal with.

Art law includes a wide range of issues dealing with the protection of the creative process, marketing, sale, and ownership of art. Disciplines including intellectual property, contract, constitutional, tort, tax, and commercial and international law must be considered. There are a number of laws and agreements that aid in deterrence, investigation, and prosecution of crimes committed against cultural properties. Others relate to theft, transport, sale, ownership of art, antiquities, remains, protected species, etc. (Lind et al. 2002).

The Hague Convention for the Protection of Cultural Property in the Event of Armed Conflict (1954) and the subsequent UNESCO Convention (1999) on the Means of pProhibiting and pPreventing the iIllicit iImport, eExport and tTransfer of oOwnership of cCultural pProperty

and mission to "maintain, increase and diffuse knowledge by assuring the conservation and protection of the world's inheritance of works of art and monuments of history," (UNESCO 1994) addresses the protection cultural properties, contents, collections art, and artwork on an international level.

Subsequent to the incident at the Isabella Stewart Gardner museum in 1990, US laws have been established to aid in the investigation and prosecution of art theft crimes. The Theft of Major Artwork Statue signed in 1994 made it a federal crime to steal from museums and libraries. It defines institutions, theft, possession transport, and types and value of property covered. It gives authority to the FBI to investigate and prosecute art- or artifact-related crimes which previously were not within their jurisdiction. Interpol, Scotland Yard, along with agencies, such as, the Art Loss Registry, has strengthened the overall identification of investigation and prosecutions related to and return of missing or stolen art (Chaffinch 2008).

Conclusion

Protection of the world's most cherished works of art, artifacts, antiquities, monuments, books, manuscripts, and endangered wildlife is a challenging and onerous task which employees nearly every facet of the security field, from the basic security guard duties to employing the most sophisticated technology. The entire spectrum of security is used to ensure that the public has the ability to enjoy viewing these priceless works while continually protecting them from theft, or damage, whether intentional or unintentional.

Cybersecurity: Incident Response

Marie-Helen Maras
Department of Security, Fire, and Emergency Management, John Jay College of Criminal Justice, City University of New York, New York, NY, USA

Keywords

Incident response · Cybersecurity · Digital forensics

Definition

Incident response refers to the containment, investigation, eradication, mitigation, and response to a cybersecurity threat.

Introduction

Incident response includes the policies, procedures, processes, practices, and communications that are designed to aid in the management of human, technical, and financial resources during and after a cybersecurity incident. Incident response is primarily concerned with containing a cyberintrusion and mitigating the harm caused by the cyberintrusion. Incident response plans are created with the understanding that it is not a matter of *if* a cybersecurity incident will happen, but *when* a cybersecurity incident will happen. An essential element in incident response, therefore, is planning for a cybersecurity incident to occur.

There is no one-size-fits-all incident response plan. The incident response plan of a private organization or government agency is determined by the organization/agency's mission, goals, assets, and available human, technical, and financial resources. There are, however, common elements within existing incident response plans across organizations and agencies. These elements are included in the National Institute of Standards and Technology's (NIST) Computer Security Incident Handling Guide (see Cichonski et al. 2012). Some of the key elements of incident response plans are explored in this chapter. In particular, it examines the three phases of incident response which describes actions taken prior, during, and after a cyber incident.

Incident Response Pre-planning

Pre-planning involves proper preparation to deal with incidents in the event that they occur, particularly, ensuring that the people, processes, and procedures that are needed for an effective cybersecurity incident response are in place. This pre-plan includes identifying priority assets and cybersecurity incidents to respond to; ensuring procedures are in place to respond to cybersecurity incidents; identifying the people, teams, and/or units responsible for responding to cybersecurity incidents; and having communication plans in place in the event of a cybersecurity incident.

Asset Prioritization

One of the key elements of preparation is the identification of what the organization/agency is protecting – particularly assets, which can be processes, people, information, financial capital, infrastructure, applications, knowledge, organization, and management. After the assets that need to be protected are identified, a determination is made as to which assets are critical to the functioning of the organization/agency and continuity of operations. These assets, deemed as priority assets, should be documented, categorized, and ranked. This priority determines the primary focus of protective measures taken during incident response and the order in which systems and operations resume after the incident. Priorities are not only assigned for response, they are also assigned for the recovery from a cybersecurity incident.

Incident Prioritization

After the assets are prioritized, the cybersecurity incidents that are of concern to the organization/agency are identified. Here, the categories and classifications of cybersecurity incidents are established. The categories of cybersecurity incidents vary by organization/agency. Some basic categories of cybersecurity incidents that have been provided by the US National Institute of Standards and Technology include malware (or malicious code); denial of service (DoS) or distributed denial of service (DDoS) attacks that prevent authorized use of systems, services, data, applications, and other resources; unauthorized access to systems, services, networks, data, applications, or other resources; inappropriate usage of networks and computers; and multiple cybersecurity incidents – whereby one incident actually encompasses two or more cybersecurity incidents (Cichonski et al. 2012).

The classifications of cybersecurity incidents vary by organization/agency. According to the International Organization for Standardization (ISO) and International Electrotechnical Commission (IEC), classifications of cybersecurity incidents are created based on parameters, the most common of which are *impact* (i.e., the damage or harm caused to the organization/agency and, by way of extension, relevant others) and *urgency* (i.e., the speed with which the organization/agency needs to deal with the cybersecurity incident) (see ISO/IEC 27001). The intersection of these parameters is used to determine priorities. For example, cybersecurity incidents with a value of 1 have both high impact and urgency and, as such, are considered critical. Organizations/agencies should respond to these cybersecurity incidents first. Following these cybersecurity incidents, those valued at 2, 3, 4, etc. should be dealt with.

Accordingly, the prioritization of incidents to respond to is not based on the sequence of the detection of the events – meaning whatever was first detected or more generally the order in which events were detected. Instead, incident prioritization is based on "the current negative technical effect of the incident (e.g., unauthorized user-level access to data) but also the likely future technical effect of the incident if it is not immediately contained (e.g., root compromise)" (Young 2013, p. 16). For example, malware may infect one workstation (which is "the current negative technical effect") but, if not contained, can spread and adversely impact the functioning of the network (which is the "future technical effect").

Standard Operating Procedure

A standard operating procedure (SOP) for common cybersecurity incidents can assist in providing the necessary guidance on incident response, by including the policies and sequential acts that should be followed in the event of a cybersecurity incident. Standard operating procedures include the "processes, techniques, checklists, and forms used by the incident response team" (Cichonski et al. 2012, p. 8). These standard operating procedures should be as comprehensive as possible and detail not only the steps to be taken in the event of a cybersecurity incident but also the priorities of the organization/agency during cybersecurity incidents.

Roles and Responsibilities

The plan should include how the incident response team (IRT; aka, computer security incident response team or CSIRT) and other individuals involved in incident response will communicate the incident to relevant stakeholders. Another key element of pre-planning is determining who has the ultimate responsibility in the event of a cybersecurity incident. Specifically, individuals who will serve as a point of contact and have a primary role in incident response should be identified. These individuals will not only be responsible for managing the cybersecurity incident but will also be responsible for communicating the actions to be taken to deal with the cybersecurity incident. Depending on the type of cybersecurity incident, these individuals may also need to communicate with other relevant stakeholders both within the organization/agency and outside the organization/agency, especially if assistance is sought from external organizations/agencies. In addition to the aforementioned roles, these individuals are responsible for investigating indicators of suspicious or malicious cyber-activity, confirming that a cybersecurity incident has taken place or is currently taking place, and proposing technical solutions to manage the cybersecurity incident.

The composition and roles of the IRTs need to be delineated. Incident response teams can have different structures (for further information on CSIRT organization models, see Killcrece et al. 2003). For example, the central IRT handles all cybersecurity incidents throughout the organization/agency, while a distributed IRT includes "multiple incident response teams [in an organization/agency], each responsible for a particular logical or physical segment of the organization" (Cichonski et al. 2012, p. 13). Another structure is a coordinating team. This type of team may provide advice to other teams; for instance, it could be a department-wide team that provides assistance to teams that are located within particular government agencies (Cichonski et al. 2012). The

IRTs can be made up entirely of employees that belong to the organization/agency. These teams may also include contractors, who conduct outsourced work with respect to incident response. Also, IRTs can be made up entirely of outsourced individuals; in this instance, contractors are on-site (i.e., at the organization/agency) and hired to be on-site to perform incident response activities. Generally, the roles and responsibilities of relevant stakeholders during a cybersecurity incident should be identified and communicated to these stakeholders. The task that each of these individuals will perform during and after the cybersecurity incident should also be established and documented. The stakeholders who are tasked with responding to a cybersecurity incident should have the relevant knowledge, skills, and abilities (KSAs) to contain and mitigate the threat. Information about KSAs for IRTs can be found in the 2017 National Initiative for Cybersecurity Education (NICE) Cybersecurity Workforce Framework (see Newhouse et al. 2017).

Communication

Proper communications are an essential element of incident response. Here, it is important to determine when to communicate information about cybersecurity incidents and in what circumstances, as well as to whom to communicate the incident and to what extent information about the incident will be revealed (Cyber Security Coalition 2015). It is also important to determine when communication to relevant stakeholders is not required, that is, when the cybersecurity incident does not need to be reported to these stakeholders (Cyber Security Coalition 2015). The method used to communicate the incident – meaning the communication means – must also be established. The individuals who will be contacted in the event of a cybersecurity incident within an organization/agency should be established. The contact information for all relevant individuals who need to be notified of a cybersecurity incident should be easily accessible and should be communicated to members of the organization/agency. What should also be communicated is when operations are to resume as normal (if these were impacted by the cybersecurity incident). This type of information is often communicated to executives, heads of departments, divisions, and units, as well as other supervisors (as needed and if deemed necessary). Within the organization/agency, some information about the cybersecurity incident should also be communicated to other employees especially if the cybersecurity incident impacted their ability to do their work (e.g., employees are unable to access the organization/agency's network and/or systems).

Having a plan to communicate information about the cybersecurity incident is essential. What is also essential is communicating the right information at the right time to the right individuals. This point applies to both internal stakeholder communications and external stakeholder communications. The policies and procedures for communicating a cybersecurity incident for internal stakeholders and external stakeholders, thus, also need to be established. With regard to internal stakeholders, the plan includes guidance on what type of information should be communicated with them. These plans often prescribe the following information to be communicated: information about what operations, infrastructure, data, and other assets were impacted by the cybersecurity incident; the type of response (i.e., the manner in which the cybersecurity incident is handled); and the expected outcome from the incident response, including anticipated short-term and long-term impacts of the cybersecurity incident (Cyber Security Coalition 2015). The information communicated depends on the cybersecurity incident. With regard to external stakeholders, depending on the cybersecurity incident and the terms of incident response plan, any of the following external stakeholders may be contacted: an affected external party; external IRTs belonging to other organizations/agencies; law enforcement agencies; the media; and Internet service provider and telecommunications providers (to name a few) (Cichonski et al. 2012; Cyber Security Coalition 2015).

The circumstances, if any, under which internal and external stakeholders are contacted and when they are contacted vary and depend on the organization/agency and the organization/agency's needs. Overall, whenever possible, those

impacted directly or indirectly by the cybersecurity incident should be contacted. Especially when communicating to external stakeholders, it is imperative that the legal, media, and or public affairs units/departments/offices within an organization/agency are involved in any external communications and that the information that is communicated is coordinated with this unit/department/office (Cyber Security Coalition 2015; Cichonski et al. 2012). The units/departments/offices that assist with communications to external stakeholders vary by organization/agency.

Communication has three basic functions: incident resolution and handling; limiting reputational harm/damage; and compliance driven (Cyber Security Coalition 2015). When the function of communication is the resolution and handling of a cybersecurity incident, the aim of communication is to transfer relevant information to other individuals who have a role and responsibility in incident response handling to contain and resolve the problems associated with the incident. When the function of communication is to limit the reputational harm or damage that could be caused as a result of the cybersecurity incident, this form of communication is directed at national and international partners, the media, the public at large, and other relevant internal and external stakeholders. Finally, when the function of communication is compliance driven, the communication must meet legal and regulatory requirements for notifications of affected individuals, and in certain instances this obligation extends to industry regulators. The legal and regulatory requirements for notifications depend on the cybersecurity incident.

Detection, Analysis, Containment, Eradication, and Recovery

In the detection and analysis phase, what is determined is whether or not an incident has occurred. Once a cybersecurity incident is detected, the cybersecurity incidents are evaluated, and decisions are made on how the cybersecurity incidents need to be addressed. The incident response plan should thus include the manner in which the organization/agency will respond to a cybersecurity incident. This plan should consider the ways in which the response to the incident will minimize damage and reduce the costs associated with response to and recovery from a cybersecurity incident and the procedures that will be followed to communicate the cybersecurity incident to relevant internal and external stakeholders (Cyber Security Coalition 2015; Cichonski et al. 2012). The response to incidents includes the specific procedures that should be followed to contain a cybersecurity event (i.e., the identification and isolation of the system impacted by a cybersecurity threat and/or the area targeted by the threat to prevent harm/damage to other areas) and to investigate and/or to resolve the cybersecurity incident (Cyber Security Coalition 2015; Cichonski et al. 2012). Particularly, this part of incident response involves the containment, eradication, forensic analysis of, and recovery from the cybersecurity incident, wherever appropriate (Cichonski et al. 2012).

There are two dilemmas associated with incident response: recover quickly or gather evidence (Cyber Security Coalition 2015). The first dilemma is whether to disconnect the network or shut down systems in order to facilitate a faster recovery. This approach is not conducive to an investigation of a cybersecurity incident. On the positive side, this approach enables a faster recovery from an incident (although this depends on the type of cybersecurity incident and whether or not full or partial recovery is possible) and enables a fast response, which minimizes the amount of time an attacker has to compromised the system, corrupt information, or steal data. On the negative side, this approach will alert the perpetrator of the cyberintrusion or cyberattack of the discovery of the incident. Also, if this approach is followed, then it is likely that vital information will be missed and lost, which means that a similar incident may be likely experienced in the future. The second dilemma involves the approach of monitoring the cyberintrusion and focusing on *digital forensics* (i.e., "a branch of forensic science that focuses on criminal procedure law and evidence as applied to computers and related devices,"

Maras 2014a, p. 29) applications in order to gather information about the cybersecurity incident. This approach is much more thorough than the one previously discussed and enables the identification of the root causes of the issue and the manner in which these issues can be resolved. This type of approach is essential for gathering evidence that could be used in a court of law (Maras 2014a). This approach, however, will delay recovery from the cybersecurity incident.

In this phase, the acquisition, preservation, securing, and documentation of evidence occur (Maras 2014a). During the investigation phase, a determination is made of the root cause of the cybersecurity incident and the magnitude of its impact. Identifying the root cause of the incident is essential to the eradication and cleanup process that follows a cybersecurity incident. This phase involves the removal of all artifacts (i.e., digital footprints) that have been left behind by the perpetrator including malware, as well as dealing with vulnerabilities identified during or after the cybersecurity incident. The severity of the cybersecurity incidents will also dictate the response. It may be necessary to quickly respond to the cybersecurity incident to prevent the harm caused to systems, devices, and networks within an organization/agency (Maras 2014a). Overall, before cybersecurity incidents, the impacts of various containment and eradication strategies should be identified, particularly the impact of these strategies on the efficacy and efficiency of operations of organizations/agencies (Kent et al. 2006).

The recovery phase includes an analysis of the cybersecurity incident and response to the incident in order to determine the procedural and policy implications of the incident and to gather information about the particulars of the cybersecurity incident, as well as to identify lessons learned with the intention of incorporating them into future activities and training (Cichonski et al. 2012; Maras 2016). An essential element in the recovery process is communications – this helps repair the reputation of the organization/agency after an incident, if this reputation was damaged due to the extent of the cybersecurity breach and the handling of the breach by the organization. Redundancy features, such as system backups, are also essential components for recovery.

Recovery planning should include the processes and procedures that are implemented to maintain operations and ensure the restoration of any assets or systems that were affected by cybersecurity incidents to an operationally ready and/or pre-incident state (Cichonski et al. 2012; Maras 2014a, 2016; Cyber Security Coalition 2015). Remediation involves repairing all affected systems and performing analyses to determine that the cybersecurity threat has indeed been contained (Cyber Security Coalition 2015). Within this phase all relevant stakeholders and individuals who are part of the incident response should be instructed on what to do to repair the harm caused, and/or individuals who were targeted in the cybersecurity incident should be instructed on what to do to protect themselves against further incidents. The restoration activities should also be coordinated with all relevant internal and external stakeholders.

Lessons Learned

The last stage involves lessons learned, which is more than determining what actually happened in the cybersecurity incident and also involves figuring out ways to improve existing processes and to better defend and protect systems, network, services, and data from future cybersecurity incidents. The lessons learned should include a detailed description of what happened; when the incident occurred; how well the incident was handled; whether procedures were followed; assessment of the adequacy of these procedures to deal with the cybersecurity incident; any actions that may have hindered or forestalled recovery; any actions that might be taken for future incidents that were not taken for the current cybersecurity incident; the measures that can and have been implemented to prevent future similar incidents or at the very least mitigate future similar incidents; and any other tools or other resources needed to detect, analyze, mitigate, and prevent future cybersecurity incidents (Cichonski et al. 2012; Maras 2014b). A post-

incident review is essential because it provides the details about an incident and any actual impacts of the incident.

Conclusion

Ultimately, the incident response plan should be detailed, updated regularly, and tested to ensure that the cybersecurity incident handling processes identified within the plan are viable. This updating is also needed to ensure that the plan is designed to provide guidance on new and emerging cybersecurity threats and new policies and procedures with respect to incident response.

Definition

Cybersecurity policy refers to a course of action adopted by a state, an organization, or a set of actors with the aim of ensuring cybersecurity and/or digital competitiveness as well as defining the individual and collective responsibilities in pursuit of that goal.

Introduction: What Is Cybersecurity Policy and Why Does It Matter?

Cybersecurity policy refers to a course of action adopted by a state, an organization, or a set of actors with the aim of ensuring cybersecurity and/or digital competitiveness as well as defining the individual and collective responsibilities in pursuit of that goal. Broadly conceived, this area of public policy concerns complex, multifaceted, and dynamic security and business innovation related to information and communications technology (ICT). Cybersecurity policymaking includes legal, regulatory, technical, organizational, behavioral, international, and other capacity-building areas. Policy dimensions attached to these include information security, network security, cybercrime, and cyber conflict.

Cybersecurity policy can be formulated and implemented domestically at different levels of government or at the international level. The policy scope can range from short- to longer-term objectives and has implications for a wide range of societal actors. Effective cybersecurity policy can have consequences for public safety, national security, citizens' well-being, and economic prosperity. As became clear in the wake of the alleged interference in the 2016 US elections, it can even have implications for the health and sustainability of democratic processes.

Some governments produce clearly articulated cybersecurity policy goals, objectives, and strategies which are publicly accessible. Others struggle to develop these due to a lack of capacity or the weight of more immediately pressing problems. Still other governments develop cybersecurity policies but choose not to share them with their own citizens or other governments. Therefore, the study of cybersecurity policy often focuses on those countries that do publish their plans – countries like (but certainly not limited to) the United States (USA), Japan, Australia, Norway, France, Germany, Canada, and the United Kingdom (UK; see http://ccdcoe.org for a list of published national cybersecurity strategy documents).

In these countries, cybersecurity policy tends to coalesce around the promotion of the national interest with security, defense, and the resilience of the private sector most often prioritized in government agendas. Specific issues tend to include the protection of critical national infrastructure and critical information infrastructure, continued industrial and business growth and innovation, the prevention of fraud, cybercrime, and child sexual exploitation, as well as defending against state-sponsored misinformation propaganda and other state-sponsored malicious cyber activities.

In a world where the pace of digitalization is accelerating, a comprehensive and well-thought-out cybersecurity policy that is based on defined legal and regulatory frameworks is understood to be a cornerstone of prosperous and proper functioning societies. However, identifying what exactly constitutes "good" cybersecurity policy is difficult for a number of reasons. This is not a mature area of policymaking and there are some factors which make it particularly challenging. These include coordination problems of any diverse policy issue across portfolios, the close interdependence of government with the private sector for pursuing cybersecurity, and the challenges of jurisdiction which sometimes defy cyber incidents.

What Factors Complicate Cybersecurity Policy?

Coordination Problems

Cybersecurity in one form or another can now be found in many (if not most) policy portfolios. In a health portfolio, cybersecurity might relate to the security of personal health records or to the safety of Internet-enabled equipment and personal health devices. Cybersecurity has implications for

international trade as governments vie for lucrative contracts for their own indigenous firms while, at the same time, a business development portfolio may be working to attract large multinational corporations by offering tax relief in order to stimulate local jobs. Cybersecurity is central to law enforcement, defense, and intelligence communities as it is seen as an important element of national security. It is not surprising that with the breadth of issues, interests, objectives, and goals among these and the many other policy portfolios engaging with cybersecurity, coordination can be extremely difficult.

Policy areas that pertain to national emergency and incident response cover a vast array of public and private cybersecurity spheres. Some of the relevant sectors include telecommunications, electrical and nuclear power, transportation, energy pipelines, weapons systems, refineries, financial networks, and healthcare systems. The effectiveness of policy is dependent upon the joint implementation between the government and the private sector. National technical authorities such as the National Cyber Security Centre (NCSC) in the UK and the National Cybersecurity and Communications Integration Center (NCCIC) in the USA have been established to monitor, collect, and share information with their partner organizations. These coordination efforts have proven particularly challenging during emergency situations due to the complexities of multi-stakeholder involvement. To communicate information in a timely and accurate way, it is important to know where clear lines of communications lie between the private sector and government agencies responsible for intelligence, defense and security, law enforcement, and commerce and finance.

Clearly, a high level of coordination is required to increase the overall effectiveness of national and local policies. At the same time, too much centralized control raises concerns about a lack of flexibility and independent thinking – both qualities understood to be important in cybersecurity. Consequently, there is a persistent tension in many countries about how to balance coordination and autonomy in portfolio-level decision-making. This leads to questions about the role that public-private partnerships (PPP) play in national cybersecurity policy implementation. This concept has been growing in prominence in recent years and now features as the centerpiece in the strategies of many developed countries.

Public-Private Partnership

Critical national infrastructures of developed countries have experienced a progressive shift toward a market-led management approach since the turn of the century. In the context of an overall shift to small government, the control over ICT estates as well as related knowledge, skills, and expertise have increasingly been relegated to the private sector rather than being retained by national governments. As a result, there has been a high level of outsourcing of responsibility, ownership, and capability to private entities. Governments regard this as a means of relieving financial burdens and remaining up to date in a rapidly evolving technological landscape. As a consequence, the PPP has now become a key mechanism for the mitigation of cybersecurity threats. Many states now rely on PPPs as part of their policy implementation plan (Carr 2016a).

PPPs are important to national cybersecurity policy for a number of reasons. In the USA, for example, over 85% of national critical infrastructure is in private hands. While there is excellence in the military and intelligence communities, commercially available ICT solutions mostly come from the private sector. Governments have an incentive to stimulate and support private sector growth and then draw on its expertise when required. While there are many reasons why the PPP is an important element of national cybersecurity policy planning and implementation, these arrangements are not without problems (ibid.).

Several types of specific PPP arrangements have been identified and classified. These include the dichotomy of horizontal, consensual decision-making partnerships which displays the true nature of PPP versus hierarchical relationships with unipolar power asymmetry. Other PPP arrangements include *partnership as management reform* through the relinquishing of state authority and capability, to *partnership as power sharing*

which entails information sharing rather than responsibility sharing. Clearly articulated (and contracted) PPPs can be very effective, but NCSSs often refer to this in an amorphous way, "we are bound together in cyberspace" (Osborne 2015) type of arrangement which fails to specify lines of responsibility and liability for national security issues. As a core responsibility of the government, national security should not be outsourced in principle, especially when the private sector has no interest in accepting it in practice.

In order for PPP to work to maximum advantage, competing agendas between the government and multinationals who own and who wield significant influence over national security concerns need to be spelled out in the PPPs' design. The distinction between the government's duty to protect national security as a necessary public "good" and profit as the ultimate end for companies needs to be explicit for the middle ground to emerge. To aid this, a shift is required from the normative and "new management" language, which obfuscates a dysfunctional partnership, to a clear language that acknowledges PPP's weaknesses.

Jurisdiction and Speed

Another set of coordination challenges that complicates cybersecurity policy concerns law enforcement investigatory capacity in response to cyber incidents. Unlike crime in the physical world, cybercrime's unique extraterritorial qualities transcend geographical boundaries. The invisible and nonlocal nature of cyberattacks creates obstacles for the authorities to quickly and effectively investigate and apprehend perpetrators.

The sheer volume and scale of potential mass targets for malicious cyber actors render conventional policing strategies ineffective. Police remit in this area includes the investigation of cyber-enabled crimes such as online fraud and child sexual exploitation imagery but also cyber-dependent crimes that incapacitate network systems such as distributed denial-of-service (DDoS) and ransomware. From personal networked devices to commercially sensitive information and from state secrets to critical national infrastructure systems, the expansive coverage of vulnerable digital assets overstretches policing resources. The blurred boundaries between national cybersecurity concerns and civilian targets, due to ever-increasing digital connectedness, also blur responsibilities.

In general, three characteristics of the virtual domain make cyber investigations extremely demanding: actor's anonymity, speed of activity, and multistage action across jurisdictions (BIICL 2014). Rid and Buchanan (2015, pp. 24–25) provide four categories in their explanation of how the speed and phasing of cyberattacks complicate an investigation. A *direct and immediate* attack can reduce uptime of servers, availability of files, or integrity of data and hardware; a *direct and delayed* attack can manipulate critical network systems to stress their components and result in physical breakdown. An *indirect and immediate* attack can cause reputation damage or loss of confidentiality through file leakage; an *indirect and delayed* attack can involve intellectual property theft which may be used to illegally gain a firm's competitiveness.

In addition, cyber attribution is an extremely difficult, if not impossible, exercise. Computer network systems allow criminals to not only conceal their tracks but also to mislead by falsifying the origin of the attack. Digital forensic evidence in this respect resists any attempts by the investigator to accurately identifying malicious actors. Bartholomew and Gurrero-Saade (2016) contend that there will never be a solid enough attribution claim to convince everyone but only multiple indicators that may lead to an educated determination as to the trustworthiness of a claim. Without the ability to attribute attacks with sufficient certainty, authorities cannot take appropriate remedial and deterrent actions (or retaliatory measures) in suspected state-sponsored attacks (ibid.).

Across jurisdictions both within and beyond a nation's borders, network infrastructure and digital connectivity can differ greatly. This creates varying levels of needs and interests for security due to an uneven distribution in the level of risks and attacks, which in turn leads to different levels of preparedness, amount of resources allocated to

law enforcement, and governance methods. Although Western countries have been working on fostering the right environment and processes and enabling cooperation and collaboration on cybersecurity policy, which is discussed below, these issues remain inherently difficult to resolve.

How Is Cybersecurity Policy Implemented?

While the governance approach for dealing with policy issues is distinct for every government, an increase in the use of a polycentric mode of governance has been observed worldwide. Such governance structure involves multiple centers and levels of decision-making within the policy community (Ostrom et al. 1961). The following discussion exemplifies the profound coordination challenges illustrated above by selectively focusing on three examples of cybersecurity policies in the USA, the UK, and internationally. It looks at some key factors affecting cybersecurity policy within the context of incident response and management. These include determining where responsibility lies and how it is delineated within PPPs, which key actors take the lead in creating and implementing cybersecurity strategies, and what are the institutional remits of the relevant agencies as well as how their work intersects to promote effective collaboration.

In the USA

In 2003, the USA was the first state to develop a national cyber security strategy (NCSS) titled the National Strategy to Secure Cyberspace and has invested heavily in policy innovation and coordination. The US National Cyber Strategy 2018 (NCS) and National Security Strategy 2017 (NSS) contain prescriptive provisions salient to cybersecurity. At the core of the policy ecosystem sits the Department of Homeland Security (DHS). The DHS conducts high-impact cybercrime investigations alongside other federal agencies. It also attempts to work with federal civilian departments and agencies to promote the adoption of common policies and to share cyber response best practices and tools. This includes the US Computer Emergency Readiness Team (US-CERT) which sits within the NCCIC, a round-the-clock awareness and incident response management center for integrated cross-government communication.

In addition, the DHS also promotes cybersecurity on several fronts through engagements with its partnering organizations. These include public awareness campaigns, cyber insurance market, research and development, jobs and training, and skills and education. Apart from the DHS, a number of US government bodies are also charged with mandates relevant to cybersecurity policymaking. For instance, the Departments of Commerce (USDC), Defense (DOD), Treasury (USDT), Energy (DoE), Health and Human Services (HHS), and Justice (DoJ) all work in conjunction with the DHS to safeguard different areas of the US cybersecurity ecosystem by jointly executing policy plans.

Notwithstanding the roles government actors take on to shape and direct cybersecurity policy at the federal level, implementation is far from a straightforward process. While the DHS's coordination role is meant to be supported by a wide range of public and private partners who are operators and co-owners of most of the government critical national infrastructures, policy delivery and outcome are often contested. Although PPP cooperation and collaboration are vital to the implementation of cybersecurity policies (which includes the NCS 2018 and NSS 2017) at the federal level, nonfederal influences are seriously impeding the effective coordination of critical infrastructure policies that aim to protect national security and facilitate cyber risk communications.

The decentralized US federalism system gives rise to simultaneous decision-making and guarding of assets and rights by different institutional actors. For instance, the US Congress, state and local governments, and private companies may choose not to share information with the federal government or adhere to federal level cyber risk guidance if doing so conflicts with their economic interests (Mussington 2018). These obstacles present significant challenges to the country's ability to carry out and maintain coherent cybersecurity policies and operational

response structures that ought to align with executive orders and legislation.

In the UK

As one of the most digitally ambitious countries in Europe, the UK's stated goal is to be "the safest place to live and do business online" (NCSS 2016–2021). Since 2011, cybersecurity has been nominated as a "Tier 1" threat to UK national security (NCSS 2011–2016). The UK has the largest digital economy of the G20, which accounts for 12.4% of the country's GDP, more than double that of the US at 5.4% (techUK 2015). Substantial resources and efforts are allocated by the UK government to ensure that the country's capabilities are at the forefront of this field.

The policy terrain of UK cybersecurity is centrally administered and funded through the Cabinet Office. Similar to the USA and other developed countries, the UK relies on the national cyber security strategy 2016–2021 (NCSS) as the overarching policy document that sets out the strategic direction of, and approach to, ensuring cybersecurity. For the years 2016–2021, the Cabinet Office oversees a budget of £1.9 billion to support the delivery of the NCSS, though they provide minimal top-down operational directives to ministerial departments involved this area.

Remaining behind the scenes, the Government Communications Headquarters (GCHQ) is the primary player leading the effort to ensure the cybersecurity of national information network and communications systems. As the technical authority within the government and the public-facing organization under the GCHQ, the NCSC supports, implements, and coordinates top-level policies. The incident response management team within the NCSC is responsible for assessing and responding to emerging incidents. If the crisis is deemed to pose an immediate threat or a rapidly escalating threat to national security, a Cabinet Office Briefing Room (COBR) meeting is convened where actors such as the National Crime Agency (NCA) may take part in a law enforcement and investigatory capacity. During emergency situations, the central government (HMG) takes action with the assistance of the NCSC to provide points of effective coordination that quickly work to deploy defensive (and offensive) measures against adversaries.

Compared to the USA, the implementation and delivery of the NCSS in the UK are functionally more distributed among HMG ministerial departments, the lead charge for which resides with the Home Office and the Department of Digital, Culture, Media and Sports (DCMS). The former is tasked with operational and strategic foci on cybercrime and cyber threats, while the latter is mandated with cyber growth, innovation, and security. Akin to the USA, the challenge of delivering national policy objectives means public and private institutions are required necessarily to work collaboratively across government and industry sectors.

Internationally

Instead of a single policy framework, the international policy landscape consists of multilateral efforts to jointly agree on rules and harmonize national laws. These comprise of clusters of binding and non-binding instruments reached by states sometimes with the help of international organizations. Binding instruments include conventions, directives, and regulations. Non-binding instruments include declarations, recommendations, and guidelines. Intergovernmental and supranational entities also work together to facilitate the implementation process in the name of global order and security, but mixed results have been obtained so far.

Launched in 2001 and came into force that year, the Convention on Cybercrime of the Council of Europe (Budapest Convention) is the first binding international treaty on crimes committed via the Internet and computer networks. Developed in consultation with the USA, Canada, Japan, and South Africa, it is open to signature by any state and at the time of writing had been ratified by 61 states. To ratify the treaty, states are required to outlaw five actions and authorize their domestic law enforcement agencies to investigate them: unauthorized access, unauthorized interception, data interference, system interference, and misuse of devices (Carr 2016b).

Predominantly an instrument for aligning states' criminal codes to facilitate faster and

more effective cooperation between law enforcement bodies, its uptake has been slow and limited mainly due to technical capability, legal factors, and a lack of political will. The addition of new protocols since 2006 has also led to widespread disagreement among states over the value of their inclusion due to inconsistencies with the public policies and security priorities of states (ibid.). The main legal mechanism upon which treaties such as the Budapest Convention can rely for cross-jurisdictional law enforcement is the mutual legal assistance treaties. Signatories of MLATs have an obligation to reciprocate in all types of criminal investigations and prosecutions Including those with a cyber dimension. Together, MLATs and the Budapest Convention significantly minimize barriers to international cooperation in the enforcement of rules and regulations stemming from cybersecurity policies.

While intergovernmental cybersecurity framework developments can be traced back to the 1990s, there has been a strong push for new policies since the early 2010s due to the novel forms of insecurity and threats that are arising in cyberspace. The "Tallinn Manual 2.0 on the International Law Applicable to Cyber Operations" contains a comprehensive analysis of how existing international law applies to cyberspace, based on the first 2013 edition. Authored by 19 international law experts led by the North Atlantic Treaty Organization (NATO), the manual's intended audience is global policymakers. According to the authors, its main contributions are that it captures the disagreements between countries on issues of cyber conflict and highlights the need to move away from an offensive posture in cyberspace to a defensive one. It acknowledges, for the first time, the lack of understanding of legal gray areas in cyberspace which creates contentions in the interpretation and application of international law (Ansley 2017).

At the UN level, states have worked together through the United Nations Group of Governmental Experts on Developments in the Field of Information and Telecommunications in the Context of International Security (UN GGE) to negotiate some common understanding and agreement about responsible state behavior in cyberspace. In 2012, all participating states (including Russia, China, and the USA) agreed that international law does apply in cyberspace. Exactly *how* it applies has been the source of ongoing debate. In 2016, the UN GGE produced a consensus report on 11 proposed "norms" of responsible state behavior, but the subsequent meeting in 2017 was dominated by deeply divergent views. The controversies surrounding the politicization of the International Telecommunication Union (ITU) are other examples, where states' different political and belief systems in the amount of control exerted over the Internet have led to the creation of internal factions which have marred its governance effort. Moreover, geopolitical rivalry is reflected in the trend toward regionalism, which impedes wider international cooperation. Different views on cyberspace governance and cyber norms are manifested in the policy stance of regional security groupings.

Notably, the Shanghai Cooperation Organisation (SCO) established in 2001 – comprised of - China, Kazakhstan, Kyrgyzstan, Russia, Tajikistan, and Uzbekistan – emphasized the importance of cyber sovereignty and the creation of a new cybercrime treaty in addition to the Budapest Convention. European Union (EU)-led frameworks such as the Network and Information Security Directive (NISD) and the General Data Protection Regulation (GDPR) tend to focus on self-regulation and compliance measures aimed at managing unavoidable cyber risks and incidents. Despite high-level dialogues between the USA, the UK, the EU member states, Russia, and China on these issues, common ground has not been reached.

Future Thinking

In the twenty-first century, the pervasiveness of software and communications systems allows cyber insecurity to permeate through every facet of citizens' lives (Tanczer et al. 2018). This presents tremendous challenges to policymaking due to the myriad of ways in which it poses potential and real harm to public interest and safety. Policymakers need to make informed decisions based on accurate assessment of the risks,

vulnerabilities, threats, and harm emanating from cybersecurity ecosystem. Yet, they are struggling to achieve this in a cohesive, joined-up way because the cyber domain is a highly dispersed issue with complex interdependencies across portfolios and it is in constant flux.

This combination of two factors produces what are referred to as "wicked problems," and they render policymaking especially challenging. These kinds of "wicked problems" need to be tackled through cross-governmental departments and intergovernmental agencies that have coexisting roles and overlapping functions. The coordination of collaborative efforts to counter these policy issues from multiple centers and levels of a policy network simultaneously, as illustrated in the examples of the USA and the UK, are key organizational features of a polycentric governance structure.

Further, adaptive policymaking (APM) and agile governance have also been on the rise globally, which are now reflected in various national cybersecurity strategies. Agile governance entails adaptive, inclusive, and sustainable policymaking that accounts for not only input from the government but emphasizes collaborative efforts by multi-stakeholders. APM explicitly accounts for deep uncertainties prompted by the speed with which technologies evolve, in contrast to the "classical approach" such as evidence-based policymaking (Haasnoot et al. 2013). APM incorporates a strategic vision and framework from which policies are derived to prepare for negative eventualities while being sufficiently flexible and dynamic to meet changing circumstances through short-term actions (Tanczer et al. 2018).

While the UK and the USA have not clarified the methodological approach behind the design, formulation, and implementation of their NCSSs, agile governance and APM models have come to be recognized as an important tool by the government, industry, and academia of the respective countries (Parcell and Holden 2013). Research on cutting-edge tools and decision-making frameworks that focus on robust evidence uptake and rigorous evidence evaluation is currently being developed to assist the policy process (Hussain et al. 2018).

In the UK, collaborative projects in partnership with government bodies such as the Cabinet Office, the Department of Work and Pensions, the Department of Health, the Ministry of Justice, and the Ministry of Defense are under way to investigate new ways of developing and incorporating agile principles in their policy work. In the USA, organizations such as NIST in the Department of Commerce, American Institute of Aeronautics and Astronautics (AIAA), and federal government infrastructure suppliers are employing an adaptive approach to policy implementation at the federal level.

These approaches are further encouraged for countries working toward common international digital development goals such as the United Nations Sustainable Development Goals. A gradual shift toward an open and inclusive model of multi-stakeholderism is advocated to account for the varied stages of digitalization of each country (Clemente 2013). Despite ongoing development in these areas, much work remains ahead. Commentators have been calling for further research into innovative APM and agile governance models on both national and international fronts and to implement their application more widely and effectively in the realm of digital policymaking.

Conclusion

The complexities of cybersecurity policy are shown through the coordination challenges, PPP obscurities, and jurisdictional issues facing the national and international policy communities. The cyber domain is throwing up uncertainties around issues of national security and national interest, which make it difficult for policy actors to make informed decisions on domestic matters or reach consensus on international concerns. These problems become particularly pronounced when decisive action is needed to respond to cybersecurity incidents and emergencies.

Although governments and private entities have devoted significant resources to better

understand and address the inadequacies, clearer terms of reference are required for effective collaboration in the policy process, and wider international cooperation is needed to resolve geopolitical roadblocks and impasse. To this end, polycentric governance appears to be the preferred approach in the USA and the UK based on how policy design and implementation are organized between the respective governments and the relevant private sector stakeholders. In recent years, research into different modes of agile governance and APM has made headway in addressing the limitations inherent to this socio-technical area of policymaking. Continued refinement of research in the areas of decision-making processes and evidence evaluation frameworks holds promise for a future that is better equipped to deal with the challenges posed by cybersecurity policymaking.

Definition

Cybersecurity involves the application and management of techniques with the aim of protecting the confidentiality, integrity, and availability of information and information assets in cyberspace.

Introduction

The widespread use of electronic information processing coupled with the emergence of business conducted through the Internet has fueled the need for organizations to protect proprietary and customer information from malicious cyber actors and nations (Grispos et al. 2017). As a result, many organizations have recognized the importance of implementing effective cybersecurity practices. According to the International Organization for Standardization/International Electrotechnical Commission (ISO/IEC), cybersecurity encompasses the preservation of confidentiality, integrity, and availability of information in cyberspace (International Organization for Standardization/International Electrotechnical Commission 2012). Confidentiality refers to "the protection of sensitive information from unauthorized disclosure" (Peltier 2013). Integrity is defined as "the accuracy, completeness, and validity of information in accordance with business values and expectations" (Peltier 2013). Availability relates to "information being available when required by the business process now and in the future" (Peltier 2013). Collectively, *confidentiality*, *integrity*, and *availability* are referred to as the CIA triad. An organization's cybersecurity objectives should be to protect the confidentiality, integrity, and availability of information and information assets within its distinct cyberspace. Various approaches can be taken to achieve this objective including through the implementation of security controls; enforcing security polices, standards, and guidelines; using risk management approaches; as well as, education and training initiatives. These approaches have existed and matured over several decades and have been classified in terms of generational waves.

Cybersecurity Waves

As part of a wider analysis into cybersecurity practices within organizations, Von Solms (2000, 2006) separated the evolution of cybersecurity countermeasures within organizations into four generational "waves". The first generation of cybersecurity countermeasures existed up until the early 1980s and can be characterized as the "Technical Wave". In this generation, cybersecurity countermeasures focused on mainframes and data centers, where solutions focused on enhancing the cybersecurity of the operating system through access control lists, user IDs, and the use of passwords. In addition, physical security barriers were also the norm. The second generation of countermeasures (the "Management Wave"), lasted from the early 1980s to the mid-1990s and emerged with management within organizations realizing that security was no longer just a technical issue. Hence, organizations needed to develop cybersecurity policies and procedures and integrate managers and executives in the security decision-making process. The third generation of countermeasures (the "Institutional Wave") started in the mid-1990s and continued into the early 2000s. This wave is characterized by the demand for organizations to implement cybersecurity standards and best practices. As a result, many organizations looked to implement standards and best practices such as the International Organization for Standardization/

International Electrotechnical Commission (ISO/IEC) 27001 standard. The fourth-generation wave (Von Solms 2006) (the "Information Security Governance Wave") developed at the turn of the millennium and emerged as a result of new legal and regulatory requirements dictating that organizations implement cybersecurity policies and processes to protect information and information systems. Therefore, this wave defines that an organization's security governance is included and part of its overall corporate governance posture.

Cybersecurity Programs

In an effort to address their cybersecurity objectives, many organizations have chosen to implement *cybersecurity programs (Grispos* et al. 2013*)*. The primary objective of a cybersecurity program is to protect the CIA triad while also ensuring that any legal and regulatory requirements are also fulfilled. Several organizations and government agencies, such as the National Institute of Standards and Technology (NIST), the International Organization for Standardization/International Electrotechnical Commission (ISO/IEC), and the Internet Engineering Task Force (IETF), have published frameworks, processes, and best practice guidelines describing how organizations can reduce cybersecurity risk and enhance their security posture.

The NIST Cybersecurity Framework

In February 2013, the President of the United States issued Executive Order 13636 – Improving Critical Infrastructure Cybersecurity. In particular, the Executive Order called for the development of a risk-based Cybersecurity Framework including industry standards and best practices to help organizations manage and mitigate cybersecurity risks. NIST answered this call to arms by publishing in 2014 a document called the "Framework for Improving Critical Infrastructure Cybersecurity," which has since been updated in 2018 (National Institute of Standards and Technology 2018). To achieve these objectives, NIST have published a series of documents, called Special Publications (SPs), that can be used either collectively or individually to secure information assets. These documents include:

- SP 800–12 provides an overview of cybersecurity security and emphasizes the importance of the cybersecurity controls and the different ways to implement them.
- SP 800–14 describes common security principles that are used and that should be incorporated within a cybersecurity policy. These guidelines can be used to enhance existing policies and develop new policies.
- SP 800–37 provides a risk-based approach called the "Risk Management Framework." The publication provides guidelines on applying the Framework to information systems with the aim of identifying what security controls are needed, how they can be implemented, and how security control effectiveness can be assessed.
- SP 800–53 specifically describes 194 security controls that could be applied to an information system in order to enhance the security and privacy of both the system and the information that can reside within the system itself.

It must be noted that while NIST has developed and published the Framework and SPs with the aim of securing critical infrastructure and federal government information systems, any organization is free to use this approach to establish a minimum security-control baseline within their specific environments (Ross 2007).

ISO/IEC 27000 Family of Standards

The ISO/IEC 27000 family of standards are an alternative set of practices that can be applied to mitigate cybersecurity attacks. The last major revision to these standards was published in 2013. While there are nearly 50 standards in the 27000 family, two main standards called ISO/IEC 27001 and ISO/IEC 27002 are considered the baseline for cybersecurity management. The ISO/IEC 27001 standard specifies how an organization can develop and implement an Information Security Management System (ISMS). An ISMS

is defined as "the policies, procedures, guidelines, associated resources, and activities, collectively managed by an organization, in the pursuit of protecting its information assets" (International Organization for Standardization/International Electrotechnical Commission 2014). Similarly, Eloff and Eloff define an ISMS as "used for establishing and maintaining a secure information environment" (Eloff and Eloff 2003). Regardless, once an organization has met the requirements specified in ISO/IEC 27001, it can become certified following the successful completion of an audit to determine it complies with the standard. The ISO/IEC 27001 standard recommends that organizations use an improvement process such as Plan-Do-Check-Act (PDCA) or Six Sigma's Define, Measure, Analyze, Improve, and Control as a method for designing, implementing, and reviewing an ISMS within their respective organization.

Within the above methods, organizations are required to identify and assess cybersecurity risks and then select appropriate security controls. ISO/IEC 27002 is a standard that provides security control recommendations, which can be used during the initiation, implementation, and maintenance of secure systems. SO/IEC 27002 consists of fourteen security domains, which cover cybersecurity control information including security policies, asset management, human resource security, business continuity management, and operations security (International Organization for Standardization/International Electrotechnical Commission 2013). The idea behind ISO/IEC 27002 is that the security controls can be applied to various organizations, irrespective of type, size, risks, or the threats faced by the organization. Hence, the range of security controls covered in the standard can also provide an organization with some flexibility to adopt only the controls that they require within their distinct environment.

IETF Request for Comments (RFC) 2196

RFC 2196 is a cybersecurity standard, formally called "Site Security," published by the Internet Engineering Task Force (IETF). The standard that was published in 1997 is intended to guide organizations during the development of cybersecurity policies and procedures to protect systems connected on the Internet. While the document might appear outdated, much of the information and practical guidance is still very much relevant to organization trying to secure their information and information assets. A range of cybersecurity subjects are covered in RFC 2196 including Firewall implementation, network security, security incident handling, policy development, and risk management.

Other Cybersecurity Practices

Depending on its type, an organization may decide to implement cybersecurity practices that have been specifically developed for its particular domain. For example, the Payment Card Industry Data Security Standard (PCI-DSS) was developed by a number of major credit card companies. The purpose of PCI-DSS is to provide consistent security controls for organizations around the world that manage, handle, and storage payment card information. At the time of writing, the current version of PCI-DSS (Version 3.2.1) was released in May 2018. Changes are usually made to the standard every 3 years. PCI-DSS specifies twelve requirements, which are organized into six control objectives (PCI Security Standards Council 2018):

1. **Build and Maintain a Secure Network and Systems**

   Requirement 1: Install and maintain a firewall configuration to protect cardholder information.

   Requirement 2: Do not use vendor-supplied defaults for system passwords and other security parameters.
2. **Protect Cardholder Data**

   Requirement 3: Protect stored cardholder data.

   Requirement 4: Encrypt transmission of cardholder data across open, public networks.
3. **Maintain a Vulnerability Management Program**

   Requirement 5: Protect all systems against malware and regularly update antivirus software or programs.

Requirement 6: Develop and maintain secure systems and applications.

4. **Implement Strong Access Control Measures**
   Requirement 7: Restrict access to cardholder data by business need to know.
   Requirement 8: Identify and authenticate access to system components.
   Requirement 9: Restrict physical access to cardholder data.
5. **Regularly Monitor and Test Networks**
   Requirement 10: Track and monitor all access to network resources and cardholder data.
   Requirement 11: Regularly test security systems and processes.
6. **Maintain an Information Security Policy**
   Requirement 12: Maintain a policy that addresses information security for all personnel.

While PCI-DSS is not legally binding within the European Union, there are some States in the United States of America where specific laws directly refer to PCI-DSS. For example, the State of Washington has incorporated the PCI-DSS standard into state law, which stipulates that compliant organizations are shielded from liability, in the event of a data breach or a security incident (The House of Representatives of the State of Washington 2010).

Another example of cybersecurity practices developed for a specific domain is the requirements described in the "Security Rule" within the Health Insurance Portability and Accountability Act (HIPAA) of 1996. More specifically, the Security Rule establishes cybersecurity standards for healthcare organizations that are legally required to protect electronic Personal Health Information (ePHI). This includes implementing appropriate administrative, physical, and technical security controls that will ensure that confidentiality, integrity, and availability of ePHI is upheld. While HIPAA provides explicit security requirements that must be implemented by healthcare organizations, an organization can select and implement security controls from various sources, including NIST Special Publications and ISO 27002.

Cybersecurity Programs in Practice

While some organizations could be legally required to implement cybersecurity practices, there are other benefits to creating, deploying, and maintaining cybersecurity programs. Siponen and Willison argue that organizations who implement cybersecurity programs can "demonstrate their commitment to secure business practices; apply for security certification, accreditation, or a security-maturity classification attesting to their compliance to a set of rules and practices" (Siponen and Willison 2009). Effectively, implementing cybersecurity programs provides an organization with a baseline for improving its overall cybersecurity management strategy.

Several researchers (Siponen 2006; Siponen and Willison 2009; Wiander 2007) have examined how organizations implement cybersecurity programs and evaluated how these programs impact an organization's wider security posture. Wiander (2007) evaluated how four organizations implemented ISO/IEC 17799 security standard. The results from this analysis showed that implementing cybersecurity programs within these organizations increased the overall understanding of cybersecurity by employees within the organizations (Wiander 2007). However, Wiander also observed that many individuals within these organizations found it difficult to implement the security standard, with the readability of the standard being one of the main problems cited during the study. Siponen (2006) made similar observations and added that many cybersecurity standards are not universally validated because they are based on personal experiences. Hence, Siponen (2006) argues that cybersecurity standards should not be treated as a "gold standard" but rather as a library of material for organizations to enhance their security posture. These concerns were further validated in a later study (Siponen and Willison 2009) when four cybersecurity standards were evaluated in several organizations. Siponen and Willison (2009) argued that when these standards are developed, they do not pay enough attention to the differences between organizations and their differing cybersecurity requirement. For

example, while a larger organization could place equal emphasis on all aspects of information security, a smaller organization might lack the demand for a dedicated security incident management team and place more emphasis on antivirus solutions and firewalls. Hence, there could be cases where some organizations are not in compliance with a particular standard because they lack the resources to segregate security functions (Siponen and Willison 2009).

Conclusions

Addressing cybersecurity effectively is an extremely difficult and complex task. This is because there is no single solution to all of an organization's security challenges. While the threat from malicious actors and nations continues to increase, organizations are under continuous pressure to identify and implement cybersecurity controls to protect company and customer information assets. One solution could involve an organization designing and implementing a cybersecurity program based on cybersecurity best practices proposed by organizations such as NIST, ISO/IEC, and IETF. However, financial constraints often limit the number and type of security controls that can be implemented within an organization. Hence, the best approach to implementing cybersecurity practices is one where an organization takes into consideration its legal and regulatory obligations while balancing the cost of security controls.

Definition

Cybersecurity preparedness assists public and private sector agencies in being ready for cybersecurity incidents that may occur and are essential for the mitigation of materialized cybersecurity threats.

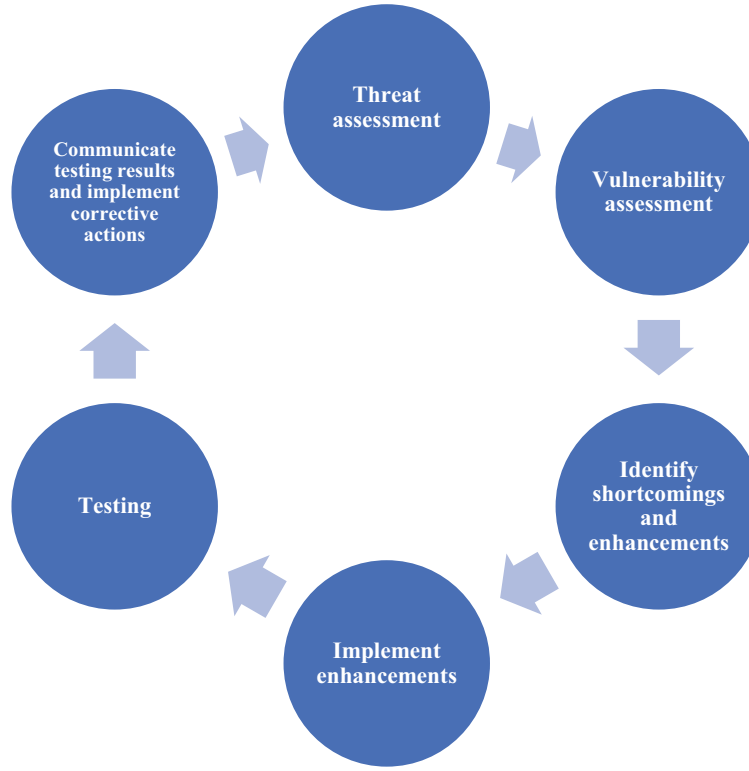
Introduction

Cybersecurity measures have retrospective and prospective capabilities. Retrospectively, these measures seek to respond to incidents while they are occurring or after they have occurred. Generally, this form of cybersecurity seeks to take action or solve something after the fact. Prospectively, these measures seek to mitigate or prevent something from occurring in the future. Cybersecurity measures, therefore, seek to anticipate threats before they materialize, forestall threats, and take action to lessen the impact of a threat once it has materialized. Having incident response plans in place is not all that is needed. These plans need to be viable and useful in the event of cybersecurity incidents to guide individuals involved in incident response on the ways in which to effectively handle a cybersecurity incident. These plans also need to be assessed.

Cybersecurity Preparedness Cycle

The U.S. Department of Homeland Security (2012) defines preparedness as "a continuous cycle of planning, organizing, training, equipping, exercising, evaluating, and taking corrective action in an effort to ensure effective coordination during incident response." Preparedness should thus not be viewed as linear activity but as a cycle (Fig. 1).

The figure in the slide depicts general phases of the preparedness cycle (between agencies and their practices, there may be variation in these phases). The first phase of the cycle is the threat assessment. Threats are circumstances that could cause unintentional and intentional harm. For instance, the hardware of digital technologies can malfunction or be purposely damaged by hackers exploiting firmware vulnerability. The second phase of the preparedness cycle is the vulnerability assessment (i.e., the susceptibility of a device to harm). Vulnerabilities in digital technologies can be found in hardware, software, and system design and configurations or can be external to the digital technologies, whereby the users of technologies may become susceptible to, for example, malware infection by way of their use of these technologies (e.g., using easy to guess passwords, opening email attachments from unknown senders, etc.). The third phase of the preparedness cycle identifies shortcomings of existing cybersecurity measures to deal with the previously identified threats and vulnerabilities (e.g., a lack of intrusion detection systems, inadequate computer-use policies, lack of cybersecurity awareness training for personnel, etc.). After these shortcomings have been identified, enhancements should be identified to deal with these shortcomings. The fourth phase of the preparedness cycle is to implement these proposed enhancements. Some professionals stop here. Stopping at this stage results in the inability to check whether the enhancements implemented are actually designed to deal with the identified threats and vulnerabilities. To determine this, the next stage of the cybersecurity preparedness cycle (the fifth phase) must be completed: the testing phase. In this phase, exercises that include cybersecurity



Cybersecurity: Preparedness, Fig. 1 General phases of the preparedness cycle

simulations (such as simulated threats targeting the vulnerabilities previously identified) are conducted to test the efficacy of the enhancements. The next phase (the sixth phase) involves the reporting and/or communication of the results of the testing and the implementation of corrective actions. Preparedness, however, should not stop there: a reassessment of the cybersecurity threats and vulnerabilities based on these corrective actions should occur.

Cybersecurity Preparedness Exercises

Cybersecurity preparedness and a well-developed and tested incident response plan are essential for the mitigation of materialized cybersecurity threats. Cybersecurity preparedness thus helps reduce adverse impacts from a cyberintrusion. Cybersecurity preparedness exercises are designed to facilitate cooperation and collaboration on responses to hypothetical cybersecurity incidents. Preparedness exercises also assist in improving coordination between internal and external stakeholders during cybersecurity events. Additionally, these exercises enhance awareness and understanding of incident response plans and potential cybersecurity threats and their impact on security. Moreover, these exercises assist in the identification and assessment of cybersecurity incident response capabilities, as well as an evaluation of the sufficiency of existing human and technical resources. These exercises, therefore, can improve response capabilities to real-life events. Furthermore, these exercises enable the evaluation of the incident response plan, identifying any deficiencies in planning and procedures and assessing or validating any modifications that have been made to the plan and procedures.

The scenarios that form the basis of many of these exercises help identify the highest priority issues, the immediate needs of an organization/business, the capabilities to improve the situation following the cybersecurity incident, the available assets to engage in incident response, and unique

and innovative solutions to respond to the incident. Cyber Storm exercises involve and are based on real-world cybersecurity incidents. There have been many iterations of the Cyber Storm exercise (the various Cyber Storm exercises can be found here: CISA 2019a). Each Cyber Storm exercise builds on the previous exercise and the lessons learned from the exercise to create more challenging scenarios for participants. Beyond Cyber Storm, the National Cybersecurity and Communications Integration Center "co-sponsore[s] the Cyber Guard exercise series, the largest tactical-level cyber exercise series in the nation, in cooperation with the U.S. Cyber Command and the Federal Bureau of Investigation" (CISA 2019b).

Types of Preparedness Exercises

Several preparedness exercises can be used to evaluate incident response plans, procedures, and capabilities. These include operations-based and discussion-based exercises (Grance et al. 2006; Dewar 2018; DHS Ready n.d.; NYS-OEM n.d.):

Operations-based exercises. Operations-based exercises are implemented in order to identify and differentiate between relevant stakeholders' roles and responsibilities during incident response and assess existing policies, plans, and procedures. There are several types of these exercises, three of which are functional exercises, full-scale exercises, and drills. *Functional exercises* enable participants to validate an organization's cyber-readiness, as well as existing cyber-incident response plans, by enabling participants in the exercise to perform their duties as prescribed by these plans during a simulated cybersecurity incident (Grance et al. 2006). The activities of participants are driven by the scenario and are not only designed to test the plans and procedures included in the plan but also participants' abilities to execute these plans and procedures. A *full-scale exercise* also enables participants to test and validate an organization's readiness, but this time this exercise is as close to a real-world cybersecurity event as possible. This exercise uses the personnel that would engage in the real-world cybersecurity event and the technical resources (e.g., equipment) they would use if a real-world cybersecurity incident occurred. Full-scale exercises are predominately conducted by government agencies. These exercises can be multiorganization and multijurisdictional and involve both first responders and many other relevant stakeholders in incident response. *Drills* are performed within an organization to systematically test a specific cybersecurity role, function, and/or process of an organization or a single unit or department within an organization.

Discussion-based exercises. As the name implies, discussion-based exercises involve facilitators who ensure objectives of the exercises are met and lead discussions regarding the exercises. The ultimate goal of these exercises is for participants to familiarize themselves with cybersecurity policies, plans, and procedures. Examples of these exercises are seminars, workshops, tabletop exercises, and games (EMI n.d.). *Seminars* include basic training for individuals involved in cybersecurity incident response, as well as other members of the organization. *Workshops* are similar to seminars but often include the creation of some output such as a draft policy or plan. These workshops are designed to familiarize individuals with cybersecurity incident response plans. These workshops are also designed to familiarize all individuals with their roles and responsibilities within these plans. *Tabletop exercises* are discussion-based, whereby facilitators guide the discussions of cybersecurity incident scenarios and participants discuss their roles during cybersecurity incidents and their responses to cybersecurity incidents. The length of tabletop exercises depends on the number of participants, the location of the participants (nationally, internationally, within or outside of one organization/agency, etc.), the type of cybersecurity incidents in the exercise, and the objectives of the exercise. *Games* are based on real-life cybersecurity events (e.g., a worst-case scenario or an anticipation of an evolution of a tactic used by cybercriminals, an evolution of the capabilities of malware, or the exploitation of some new technology by illicit actors in order to cause harm). An example of a wargame, Digital Pearl Harbor, was conducted by

the US Navy War College in 2002 that involved a coordinated and cross critical infrastructure cyber-attack (Wilson, 2003).

Red Team/Blue Team Exercises

Taking a leaf out of the military's playbook, red team and blue team exercises can and have been implemented in private and public sector cybersecurity preparedness (Brangetto et al. 2015; Dewar 2018). The red team/blue team exercise, originally used in the US military in war gaming, enables the application of information learned in trainings and classrooms to hypothetically create a cybersecurity threat based on research of threat and plan of response to this threat.

The red team portion of the exercise seeks to identify the motivations, intent, tactics, targets, techniques, methods of operation, and capabilities of assigned cybersecurity threats (e.g., advanced persistent threats or APTs, hackers, etc.). The red team behaves like a threat actor (e.g., an APT or hacker) and creates a hypothetical cybersecurity incident based on what is known about the threat actor and the threat actor's capabilities. The blue team creates a cybersecurity strategy based on the information presented by the red team. The blue team examines measures that have been used to deal with the threat actor in the past, identifies flaws and gaps in these measures, identifies how it will respond to the cybersecurity incident identified by the red team, and recommends appropriate cybersecurity measures. A modified version of a red team/blue team exercise can be used in the field of cybersecurity as a tool to think about the entire cybersecurity preparedness cycle to deal with cybersecurity threats.

Creating a Preparedness Exercise

The first step in creating a preparedness exercise is to assess the current needs and capabilities of the agency with respect to incident response. The next step involves reviewing the incident response and or crisis management plans and identifying and reviewing the roles and responsibilities of individuals responsible for incident response. The next step is the identification of potential scenarios for cybersecurity incidents. These scenarios are used as the basis for the exercises that are developed. When drafting the exercise and the instructions for the exercise, it is important to include what the objectives of the exercise are and the metrics used to assess the performance of participants. The exercise should also include a segment which will enable participants to receive feedback on their performance and to identify any areas of improvement that are needed for the plan. The latter can include discussion that is held at the end of the exercise in a way to solicit feedback from participants and identify possible areas for improvement of the plan. This feedback and evaluation of the exercise can be provided within an evaluation form at the end of the exercise at the conclusion of the exercise. Following the completion of the exercise and after-action report is completed that documents the incident, actions of participants, and provides suggestions for plan improvement. This after-action report should be distributed to management and supervisors as well as other relevant stakeholders. Lessons learned should be communicated to these participants as well as to all employees within an organization who have some role in incident response. Any policy, procedure, and/or cybersecurity measure that has been identified as needed to deal with the cybersecurity threat of the scenario should also be implemented. Plan-based exercises are essential – they generate muscle memory for cybersecurity incident response, and they make the process and decision-making that occurs during cybersecurity incidents second nature to relevant stakeholders under conditions of stress.

Conclusion

Evaluating past responses to cybersecurity incidents and their impact on agencies and US national security interests provides practitioners with better insight as to how to handle such situations more effectively in the future. New threats emerge and existing threats evolve. Cybercriminals learn how to adapt to cybersecurity

measures; for this reason, it is important to consider cybersecurity as a continuous process that should adapt to changes in technologies and criminals' methods of operation.

Data breach · Data security · Data availability · Data management · Top secret data

Definition

Information: Anything that contains something which is timely delivered and will be useful to an audience.

Data: Binary bits stored on a digital media and processed by a processor. The bits can represent different types of information, text, audio, image, video, depending upon the software tool used to process the data.

Data security: Protection of digital data from unauthorized access, unintended modification, or fabrication, and ensuring safe delivery to authorized recipients.

Data breach: Unauthorized access to data.

Hardware: Digital devices that process, transmit, and store binary data.

Software: Programming codes that process binary data.

Introduction

We are living in a digital society where all our personal, social and professional activities involve either generation, processing, or storage of digital data. Every organization, small or large, private or federal, technical or nontechnical, deals with a huge amount of digital data, which contains either confidential, proprietary, or legal information; some may even be state top-secret information crucial to national security. With the growth of Internet, digital and communication technologies, and mobile applications, use of data is increasing at an exponential rate (Gartner 2018). This growth, in turn, raises the serious concerns of data security (Stalling and Brown 2018; Whitman and Mattord 2016). Protection of data from malicious attacks has become a great challenge for research and development (Muhleisen 2018).

The objective of this chapter is to present some fundamental concepts on the data security and protection techniques. It will begin with the basic characteristics of data from security perspectives. Threats to data will be discussed. Then different approaches to protect the data, including technological and sociological, will be presented.

Data Basics

From digital point of view, data is simply a series of binary 1's and 0's stored in some electronic,

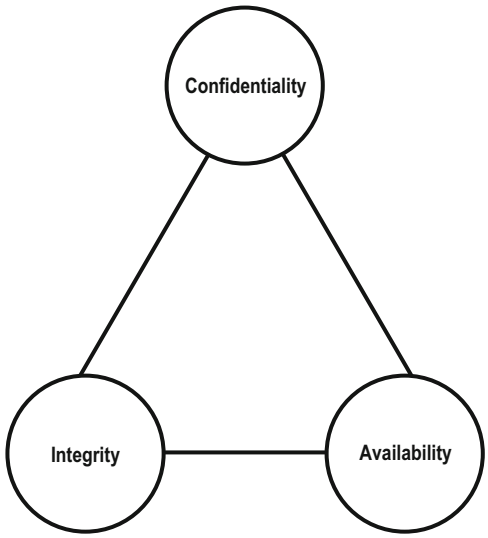
optical, or magnetic medium or transported through a network connection. Different groups of digital data represent different types of information, which could be text, graphics, audio, or video type. It is the set of hardware and software that translates between specific information and digital data. Therefore, security of data is primarily based on the type and importance of information.

"Information" is characterized by both "knowledge" and "communication" (Muhleisen 2018). Knowledge is recorded in some form, i.e., text, graphics, audio, video, and then is conveyed to its authorized user. Therefore, information is analyzed in security field by three main characteristics, namely, confidentiality, integrity, and availability (CIA). The first two characteristics connect to "knowledge," while the third one refers to "communication" of information. Information characteristics are often explained using a CIA triad as shown in Fig. 1 (Stallings and Brown 2018).

1. **Confidentiality**: Data is disclosed to only its authorized users. Any exposure to an unauthorized entity destroys the confidentiality of information, which may cause severe damage to the entities involved to the data.



Data Protection, Fig. 1 CIA triad of information security (Stallings and Brown 2018)

2. **Integrity**: Data remains whole, complete, and uncorrupted. Any malicious attack or simple technical failure may impact the consistency and accuracy of data which destroys its trustworthiness.
3. **Availability**: Data is available to its authorized user when asked for. Any interference or jamming in the communication medium or technical failure may cause unavailability of data which destroys the purpose of the information.

In addition to the above three prime characteristics, data is also described by a number of other parameters, some of which are listed below.

1. **Accuracy**: The data delivered to the end user must contain the correct information. If the information is false or manipulated, the data loses its accuracy.
2. **Authenticity**: The data communication includes the information about the source/sender. It must be received from the right source as it pretends to be.
3. **Utility**: The data must have some value or meaningful purpose to the end user when received.
4. **Possession**: The source/sender and the destination/receiver must have appropriate legal rights concerning the data.

Data is also characterized by its state, which includes:

1. **Storage**: Data is saved in a medium, which determines the accuracy and integrity of data.
2. **Processing**: Data is processed using hardware and/or software, which determines the utility of data.
3. **Transmission**: Data is traversing a network, which determines authenticity, integrity and availability of data.

Data Security

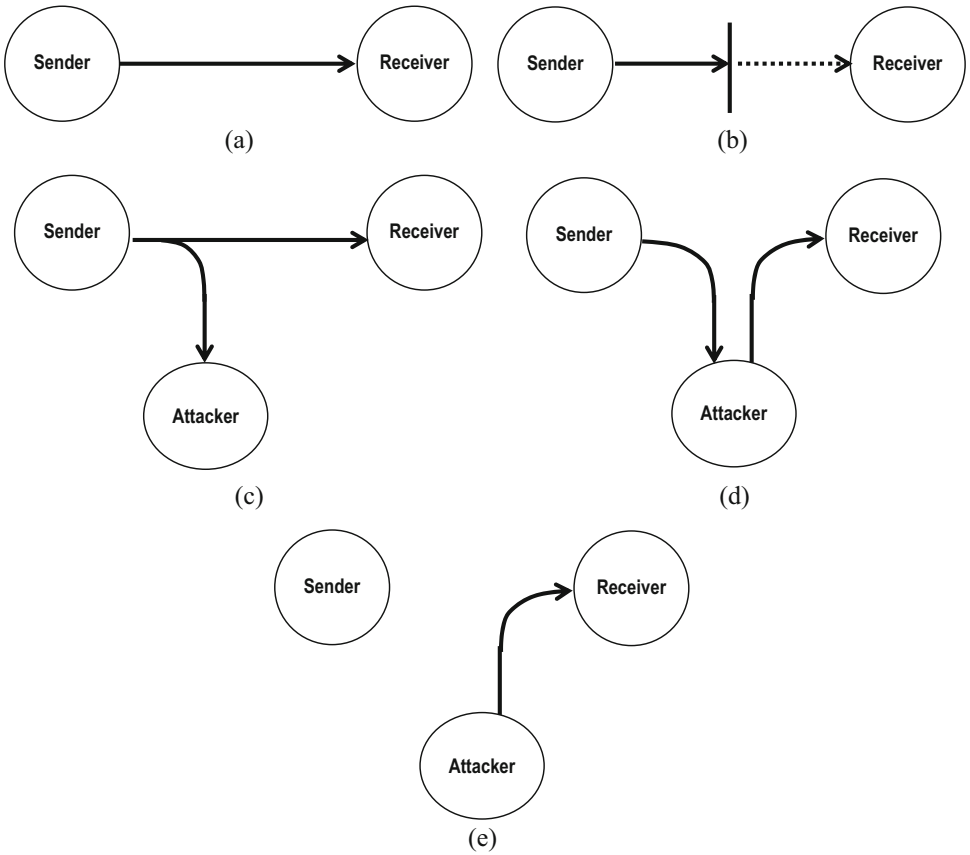
Before we talk about data protection, we need to understand how data can be hacked and hence loses its characteristics. As data is processed,

stored, and transmitted using widely available digital technologies, it is vulnerable to a variety of threats. As a result, security of data and hence information is very crucial to individual, organizational, and even national interests. Typical motives for malicious attacks on data include the following (Whitman and Mattord 2016).

1. Status: Some people, who are computer savvy, play with software tools to destroy or manipulate some data just for fun.
2. Revenge: People may take revenge by misusing some confidential data. For example, a terminated employee may destroy the company data.
3. Economic gain: People or competing organizations may attack secure data for financial purposes.
4. Political achievement: Use of cyber domain is increasing for political movement, propaganda, spying and even civil war.

There are many different ways that confidential data can be attacked. Most of the attacks are involved to the communication network as shown in Fig. 2a. The attack techniques can be categorized into the following four main groups (Fadia and Zacharia 2008).

1. Interruption: The communication between the sender and the receiver is interrupted or the source system is attacked such that the receiver cannot get the requested service from it as depicted in Fig. 2b. The availability characteristics of data are lost.



Data Protection, Fig. 2 Attack technologies: (**a**) ideal communication network, (**b**) interruption, (**c**) interception, (**d**) modification, (**e**) fabrication

2. Interception: Figure 2c demonstrates how an unauthorized party intercepts the communication silently without the knowledge of sender or receiver and gets access to data. Data is no longer confidential.
3. Modification: The attacker interrupts the direct communication between sender and receiver and diverts the data to itself as shown in Fig. 2d. Then it sends the modified data to the receiver. The integrity of data is lost.
4. Fabrication: The attacker sends false data to the receiver pretending itself as a legitimate sender as demonstrated in Fig. 2e. The authentication of data fails.

Data Protection

Data protection is a complex process because it involves multiple different entities. In general, a data system includes the following components (Stair and Reynolds 2017):

1. Hardware
2. Software
3. Data
4. Network
5. People
6. Procedure

Threats to data can occur from any of the above components. As a result, a comprehensive data protection strategy needs to include the following three approaches:

1. Technology
2. Policy
3. Education

In each of these categories, there is no single solution, rather a combination of multiple strategies.

Technological Solutions to Data Protection

Technological solutions depend on the status of data, whether in storage, or processing or in transmission. There are three main principles of data protection techniques:

1. Preventing access to data
2. Making data unreadable
3. Monitoring data

Preventing Access to Data

The best approach is to make the confidential data completely inaccessible by any unauthorized party. Several techniques can be incorporated which will control and even block the communication to the data to be protected.

Firewall: A hardware technique or a software tool or a process or a combination to control and monitor the access requests to any data. Usually placed in the perimeter of a network, it checks for any malicious code or suspicious network communication to and from the data source.

Proxy Server: Conceals the secure data source in a network by isolating from the external network. Ensures the anonymity of internal hosts and acts on its behalf to receive, process, and respond to any data communication requests from outside network.

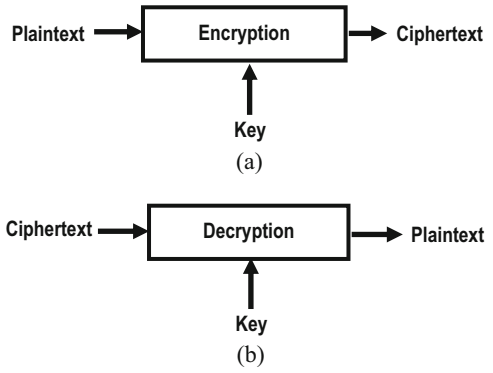
Bastion Host: System designed to represent the internal network to the outside world and withstand any attack targeted to secure data or systems.

Device Authentication: Any device plugged into a system or network needs to be authenticated before accessing or processing data.

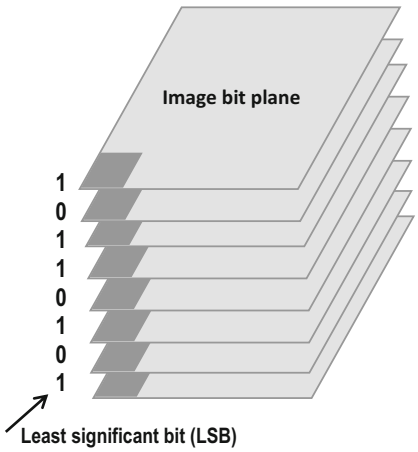
Making Data Unreadable

Data is scrambled or hidden so that an intruder cannot read or interpret the data even if he/she gains access to it. There are two main data scrambling techniques:

Cryptography: Convert the data to a different form such that it is either unreadable or unusable by any intruder. A mathematical or logical algorithm translates the plaintext data using a single or a set of secret keys to a ciphertext data as demonstrated in Fig. 3. Only an authorized user having the right key can decrypt the ciphertext data back to plaintext data and then use it. Cryptographic techniques vary in encryption/decryption algorithms and selection and management of secret keys.



Data Protection, Fig. 3 Cryptography principle: (**a**) encryption, (**b**) decryption



Data Protection, Fig. 4 Steganography principle

Steganography: Process of hiding data inside other data which can be open to public. The most popular technique is hiding the data inside an image. The image before hiding data is called a cover image and that with data hidden is called a stego image. As shown in Fig. 4, the least significant bits of pixels are replaced by the confidential data such that the overall intensity or color of the stego image will not be significantly different from the cover image. There are more complex algorithms for choosing bits from the cover image and replacing them with data bits (Islam et al. 2015). Similarly, the confidential data can be hidden in a text message between alphabets by altering the given bits.

Monitoring Data

A hardware or software or a combination tool can be designed to constantly monitor all of the activities with data in all three phases of data, storage, processing, and transmission. It logs each activity, distinguishes between authorized and suspicious activities, and generates alert messages for the data owner, user, or manager. In a network, it performs intrusion detection live. A smarter tool can also be designed to stop the suspicious activity as soon as it is detected.

Law and Policy for Data Protection

As data involves human users, in addition to hardware and software, only technological solutions cannot ensure data protection. Therefore, data protection approaches involve laws and policies.

Data Protection Act

European Union's General Data Protection Regulation (GDPR) was transposed into the United Kingdom's law as the "Data Protection Act 2018" to control personal information used by any organization. It ensures the proper use of data.

1. Data is used fairly, lawfully and transparently.
2. Data is used for specified and explicit purposes.
3. Data is used in a way that is adequate, relevant and limited to only what is necessary.
4. Data is accurate and, where necessary, kept up to date.
5. Data is kept for no longer than is necessary.
6. Data is handled in a way that ensures appropriate security, including protection against unlawful or unauthorized processing, access, loss, destruction or damage.

The Act gives an individual the following rights on a personal data stored by an organization.

1. Know how the data is used.
2. Access the data.
3. Update any incorrect data.
4. Erase data.
5. Stop or restrict processing the data.

6. Receive and reuse data for different services.
7. Monitor how data is processed in certain circumstance.

Security Policy

A data protection policy is usually designed by an organization to govern the data usage and prosecution procedure. A typical policy typically includes the following components:

1. How to use the organization's data resources safely.
2. How to respond to any data breaches.
3. What defenses should be incorporated.

There are certain guidelines on how to devise an effective data protection policy (Whitman and Mattord 2016):

1. It needs be comprehensive and include all possible scenarios.
2. It should be open to revisions and updates.
3. It should be simple and easy to understand.
4. It should define what data and activities are subject to organization policy.
5. It should be available to all data users.
6. There should be a procedure to enforce the policy while data is in use.
7. Users should be warned about the penalty for mishandling data.

Security Awareness

No matter how sophisticated technology is implemented and/or how vibrant policy is devised, data will not be safe unless the human users are well educated and well aware of consequences of data breaches. The users must understand the significance of data to the organization, learn the technology and how to use data, and realize the penalty for policy violation.

Security awareness can be incorporated through a number of activities as follows.

1. Security Training: The users need be trained on the data usage and protection schemes. Such training must be included in the new-employee orientation program. In addition, there should be frequent workshops and seminars to keep them updated on the data protection technique and policy.
2. Security Drills: Like fire drills, security drills can be designed and implemented in order to assess the users' performance in case of malicious incidences.
3. Security Alerts: Warning messages, emails, pop-up windows, and several other strategies should be adopted to keep the users aware of data protection techniques and policies.

Conclusion

Digital data contains confidential information that are crucial to individuals, organizations and the nation. Data needs be protected from access, modification or destruction by any unauthorized party. There are three approaches to protect data, namely, technology, policy, and education. Technological schemes involve hardware and software tools to prevent access to data, hide data from intruder, and constantly monitor the data operations. Laws and policies reserve the rights of different entities involved to data, namely, users, owners, senders, and recipients. Finally, security awareness programs, including training, drills, and alerts, educate the users and keep them updated on the safe usage of data.

The world is moving around digital data which are very vulnerable to many different types of attacks. The most challenging part is that the hackers are always developing new attack technologies. Therefore, data protection techniques should be innovative, dynamic, and proactive. All three approaches to data protection, technology, policy, and education need to function efficiently, in synchronization and in depth in order to defend against any malicious attack on data.

Definition

Department of Homeland Security: a federal agency, created in the wake of the terrorist attacks of 9/11, tasked with leading the national effort to protect the United States from terrorism

Introduction

The Department of Homeland Security (DHS) is a federal agency originally created to counter the threats of terrorism but has expanded its responsibilities to combat crime and provide expeditious response and support during emergencies. Currently, the DHS core duties include preventing terrorism and enhancing security, securing and managing borders, enforcing and administering immigration laws, safeguarding and securing cyberspace, ensuring resilience to disasters, and maturing and strengthening the homeland security enterprise.

The current mission of the DHS is "With honor and integrity, we will safeguard the American people, our homeland, and our values" (DHS

2016). However, the DHS cannot effectively protect the homeland alone. Evolving threats, expansive skillsets of malicious actors, and vulnerabilities to critical infrastructure create a difficult and complex operation for the DHS. Through its cooperation with the federal government and state, local, tribal, and territorial (SLTT) partners, as well as its relationship with the private sector, the DHS is better equipped to meet growing security needs.

Over the past 16 years, the DHS has faced several challenges and criticisms. From its massive size to its multibillion dollar budget requests, skeptics consistently call into question the DHS's capabilities and successes. Dynamics within the DHS's operational constructs and external political factors have impacted the many ways Americans view the organization and the future of homeland security.

History

Though the origins of homeland security are often associated with the devastating attacks on 9/11, domestic terrorism has been a concern for the United States government and the American people since the nineteenth century (e.g., the Black Panthers, the Ku Klux Klan, the Workers Party, the communist agitators, the Students for a Democratic Society, the Weathermen of the Vietnam Era). According to Nemeth (2017), "the concept of terror against governing authority was entrenched into the political and social fabric of these organizations" (p. 15). The United States had also experienced international terrorism pre-9/11, at home and abroad (Nemeth 2017). Though terrorism was not a new term during the pre-9/11 era, the concept of homeland security was not as widely understood.

Prior to 9/11, Islamist extremists had provided "plenty of warning that they meant to kill Americans indiscriminately and in large numbers" (9/11 Commission Report, 2004, para. 9). On home soil, the 1993 WTC bombing that killed six was led by Ramzi Yousef, who also planned to blow up United States airliners over the Pacific in 1995 (9/11 Commission Report, 2004). Overseas, there was the 1983 terrorist attack against the United States Marine base in Beirut, Lebanon, which killed 241 servicemen (Nemeth 2017). In 1998, there were several truck bombings at US embassies, carried out by al-Qaeda, in Nairobi, Kenya, and Tanzania (9/11 Commission Report, 2004). Though not as sophisticated as the coordinated attacks on 9/11, these terrorist attacks, among several others, should have indicated to law enforcement and the intelligence community that Osama bin Laden's al-Qaeda would continue to relentlessly target Americans.

In the weeks and months following the attacks on 9/11, it became apparent that there were operational, intelligence, aviation security, and border and immigration control issues (9/11 Commission Report, 2004). In reviewing and evaluating such failures, the Bush administration made it a priority to never let another attack like 9/11 happen again. In November 2002, the Homeland Security Act was stood up to create the DHS. This Act, which created offices and directorates within the DHS, reflected the concept that terrorism prevention was now at the forefront of security. As years passed, additional DHS laws concerning emergency management, immigration and border security, maritime security, and transportation security were also passed.

Organization

Since its inception, the DHS operational and support components were brought together to serve as one unified front. Currently, there are 14 agencies operating under DHS supervision (see Table 1). As expected, the Office of the Secretary has changed and developed since its early beginnings, housing several other offices, including the Office of Public Affairs, Privacy Office, and Partnership and Engagement. On December 6, 2017, Kirstjen Nielsen was sworn in under President Trump as the sixth Secretary of Homeland Security and has focused on the immigration laws and policies that have been at the center of President Trump's administration. However, this is not to say that Secretary Nielsen's attention has not been focusing on other issues, for example, election

Department of Homeland Security (DHS), Table 1 Agencies under DHS supervision

Countering Weapons of Mass Destruction Office	Cybersecurity and Infrastructure Security Agency	Federal Emergency Management Agency	Federal Law Enforcement Training Center
Office of Intelligence and Analysis	Office of Operations Coordination	Management Directorate, Science and Technology Directorate	Science and Technology Directorate
Transportation Security Administration	United States Citizenship and Immigration Services	United States Coast Guard	United States Customs and Border Protection
United States Immigration and Customs Enforcement	United States Secret Service		

interference. Secretary Nielsen recently said, "Election security wasn't a mission we envisioned for the department when it was created, but it's now one of my highest priorities" (Tuttle 2018, p.20). These examples demonstrate that DHS handles much more than what typically is believed to be in its purview.

Another construct within DHS is its several advisory panels and committees, which provide guidance on mission-related topics. Mission-related topics include academic engagement, counterterrorism committees and working groups, and immigration committees and working groups, among others. Of great prestige is the Homeland Security Academic Advisory Council, which "provides advice and recommendations to the Secretary and senior leadership on matters related to homeland security and the academic community, including: student and recent graduate recruitment; international students; academic research and faculty exchanges; campus resilience; homeland security academic programs; and cybersecurity" (DHS 2018a, para. 1). These advisory panels and committees are just a small sampling of the programs DHS has in place for engaging with Americans and the private sector.

Public-Private Partnership

The DHS has established several programs and campaigns to bring awareness to critical infrastructure owners and operators, as 85% of critical infrastructure ownership belongs to the private sector (U.S. GAO 2006). This high percentage of ownership is attributed to:

> 1.) the perception that the private sector is better placed to efficiently manage different sectors of activity, including security ones, thanks to its organizational structure and existing expertise; and
> 2.) the enlargement of the concept of critical infrastructure, which evolved from being equated with military structures to being associated with more diverse forms of infrastructure such as economic ones. (Bures and Carrapico 2017, p. 232)

As such, since majority of stakeholders represent the private sector, public-private collaboration is a necessity.

The homeland security enterprise benefits from public-private partnerships, as they can enhance hiring, resource utilization, specialization, cross sector trust, and technological innovation (Busch and Givens 2012). Additionally, partnerships aid in intelligence sharing, which can lead to swift response during emergencies and terrorist attacks. These partnerships go beyond contractual agreements and government-business relationships and instead represent a more dynamic and meaningful collaboration to contribute to homeland security than any one agency could alone.

The Presidential Policy Directive 21: Critical Infrastructure Security and Resilience recognizes 16 critical infrastructure sectors (see Table 2). Though each sector serves the interests of the American people in a different capacity, interdependencies exist across sectors. The holistic vitality of the entire critical infrastructure system is interconnected, and if one sector were to be incapacitated, the entire system would be left vulnerable.

Department of Homeland Security (DHS), Table 2 16 Critical infrastructure sectors

Chemical	Commercial facilities	Communications	Critical manufacturing
Dams	Defense industrial base	Emergency services	Energy
Financial services	Food and agriculture	Government facilities	Healthcare and public health
Information technology	Nuclear reactors, materials, and waste	Transportation	Water and wastewater systems

Several public-private programs have been established to bring awareness to critical infrastructure homeland security issues and to problem solve difficult issues pertaining to critical infrastructure vulnerabilities and threat exploitation. For example, the DHS Science and Technology Directorate Silicon Valley Innovation Program was established to find "new technologies that strengthen national security with the goal of reshaping how government, entrepreneurs, and industry work together to find cutting-edge solutions" (DHS, n.d. para. 1). Other programs, such as the SAFETY Act, which support the development and deployment of anti-terrorism technologies, provide incentives to partners. These programs aid in the flow of intelligence sharing between the public and private sector.

A major facilitator of intelligence sharing is through the National Framework of Fusion Centers. A fusion center is a state and major urban area focal point for the receipt, analysis, gathering, and sharing of threat-related information between the Federal Government, SLTT, and private sector partners (DHS 2018c). A fusion center may seat representatives from a variety of law enforcement and emergency services disciplines, and, in theory, this "diverse composition of organizations is best positioned to identify and understand threats facing a particular jurisdiction or region" (Carter et al. 2017, p. 11–12). The fusion center engages local and regional partners on all threats and all hazards, serving as the one-stop shop for homeland security and crime requests and inquiries.

The Boston Regional Intelligence Center (BRIC), an urban area fusion center in Massachusetts, works with the private sector through the BRIC Shield. The BRIC Shield is a membership program that provides customers with threat information and situational awareness (BRIC 2018). Through this membership, private sector partners stay abreast on pertinent homeland security and crime issues. Other intelligence sharing programs within the BRIC and fusion centers across the country exist, including the Homeland Security Information Network, which is the trusted portal for sharing unclassified information (HSIN, 2018).

Hometown Security

In recent years, safety and security for soft targets and crowded places have become a focus for policy makers and public safety professionals. Places that are publicly accessible, where people gather freely, such as concerts, sporting events, subways, or malls, and have minimal security are vulnerable to attack (DHS 2018d). These types of areas have been intensely targeted in the past as they provide unsophisticated means for a malicious actor to carry out an attack. Attacks may include improvised explosive devices, vehicle ramming, or mass shootings.

Unfortunately, active shooter incidents in populated areas have drastically increased in recent years. In 2016 and 2017, there were 50 incidents in 21 states resulting in 943 casualties, 712 casualties from 2014 and 2015, which experienced 20 incidents in 26 states resulting in 231 casualties (FBI, 2018). And, within the first 45 days of 2018, there were 17 school shootings (Galea et al. 2018). On February 14, 2018, the Marjory Stoneman Douglas High School shooting, which resulted 17 causalities, led to "unprecedented action, including some of the largest and most prominent gun dealers and retailers, such as Dick's Sporting Goods and Walmart, [to] voluntarily [stop] the

sales of assault weapons and [increase] the age at which customers can buy certain firearms" (Galea et al. 2018, p. 858). Such horrific acts of violence have led not only private sector companies to forge change but also the DHS through its hometown security programs.

One of the more popular programs is the "If You See Something, Say Something" campaign. This program encourages citizens to stay alert and report suspicious activity to local law enforcement to protect the community (DHS, n.d.). The DHS has designated September 25 as National Awareness Day, indicating that "informed, alert communities play a critical role in keeping our nation safe" (DHS, n.d., para. 2). Aside from this campaign, DHS also provides the community with free and accessible resource guides and threat assessment models. The people living and working in any community are the eyes and ears for law enforcement.

Perception of DHS

As with all major legislative laws and policies, especially those related to the DHS, researchers, academics, and practitioners undoubtedly point out flaws and challenges within the Department. When the 2002 Office of Homeland Security's National Strategy for Homeland Security was introduced, it came under scrutiny for various reasons including its "fuzziness of roles and responsibilities across existing and planned homeland security programs" (Caudle 2003, p. 22). Given the sheer size of the DHS, which today requires the employment of over 240,000 workers, it is not farfetched to believe that transparency and efficiency are overshadowed by bureaucracy and misplaced power.

Even after the first 10 years of operation, it was still believed by some critics that DHS and its Science and Technology Directorate were underperforming. Again, pointing to the "heterogeneous and immiscible collection of agencies with different cultures, policies, traditions, missions, and responsibilities," it was ascertained that a unified effort was merely inconceivable (Zimmerman 2011, p. 153). The issue was not that intentions were misplaced but instead that the strategies that were implemented were completely misguided and illogical. One of the major concerns with the Science and Technology Directorate was its budget. From the start, the Science and Technology Directorate was criticized for "funneling funding exclusively into the Department of Energy national laboratories, rather than supporting university-based programmes or private-sector research" (Zimmerman 2011, p. 154). It is believed that the allocation to these labs "may have precluded the innovations that might have come from a more broadly sourced effort" (Zimmerman 2011, p. 154).

The concern for misplacement of power and funding has been covered recently in mainstream news media, especially when considering the detention of immigrant children. It is believed the DHS facilities do not meet the "basic standards for the care of children in residential settings" and that there should be "limited exposure of any child to current DHS facilities (i.e., Customs and Border Protection and Immigration and Customs Enforcement facilities)" (Linton et al. 2017, p. 1). It has been reported that many detention centers lacked bedding and bathing facilities, did not provide sufficient food or water, and kept children and families in extremely cold temperatures (Linton et al. 2017, p. 4). These conditions, coupled with the separation of children from their biological parents or legal guardians (when unable to prove relation), have traumatized detained children.

Conclusion

The DHS is a young federal agency tasked with a major responsibility – keeping America safe. Since 9/11, the prevention of terrorism has been at the forefront of security professionals' minds. From major event protection to school safety, from aviation security and cybersecurity, the DHS has its hands in all mission-related operations. Though the future of homeland security is unclear, the fact remains that as long as terrorism exists, so too does the need for enhanced security, forward thinking, and meaningful decisionmaking. For the DHS to thrive in the

coming years, it cannot "use law enforcement techniques suitable for the twentieth century" (Nemeth 2017, p. 531). Instead technology needs to be researched and put to efficient and reasonable use as it pertains to preventing terrorism and crime and responding to natural disasters.

Drone · Unmanned aerial vehicle · Unmanned aircraft system · Remote sensing · Surveillance · Privacy · Reconstruction

Definition

A drone, otherwise referred to as an unmanned aerial vehicle (UAV) or unmanned aircraft system (UAS), is a remotely piloted aircraft that is typically controlled via a handheld transmitter, computer-based ground station, or an onboard computer, when operating autonomously.

Introduction

Unmanned aircraft systems (UASs) or unmanned aerial vehicles (UAVs), otherwise known as drones, are becoming increasingly commonplace among law enforcement worldwide. As UAV devices are providing operators with real-time situational awareness while replacing personnel in tasks considered to be too dull, dirty and dangerous (Marshall 2004). Previously, drone technology only encompassed large military systems deployed overseas for reconnaissance and combat use. However, over the last decade, the emergence of sophisticated micro aerial vehicles (MAVs) and smaller UAVs (<20 kg) has led to the use of UAV technology across every sector. As a result of this, UAV technology is also increasingly used internationally among emergency first responders and law enforcement as a low-cost tool for tackling crime and responding to mass incidents. This is because UAV technology has the ability to provide operators with real-time situational awareness, by assessing large and potentially hazardous environments from new perspectives, using a range of data capture methods, without having to factor in high staffing costs or risk to personnel.

Although increasing use of UAV technology has predominantly been positive, criminal and terror groups have also found ways to profit from the utilization of drone technology, with increasing incidents occurring worldwide. Consequently, illegal use of drone technology is a prevalent issue facing law enforcement agencies and governments. However, citizens and businesses are also using drones for recreational and security purposes. As such, crucial decisions are currently being made regarding how to police, search, and seize criminal UAV devices, as well as to manage the illegal activity by criminals. Lawmakers and enforcers are also attempting to determine the best way to preserve a safe airspace for noncriminal users while ensuring the safety and privacy of the public in general.

This entry provides an overview of UAV technology used by emergency and security management personnel for crime prevention and emergency assistance. Specifically, an explanation of UAV technology has been included to aid readers' understanding of these devices and their capabilities within different scenarios. Section "Drone Principles, Systems, and Payload" of this entry explores different drone technologies, summarizing their general characteristics and components. The aim is to inform practitioners about these devices, whether encountered as a tool within law enforcement or as an evidential item seized during investigation. Section "Criminal Drone Use and Threats to Security" summarizes how criminals use drones, with examples of

previous incidents that have caused security breaches or damage. Section "Drone Use in Law Enforcement" describes current law enforcement drone use, outlining the different applications of how police officers and other emergency first responders use this technology. Finally, Section "Drone Legislation and Public Perception" outlines general drone legislation for both members of the public and law enforcement.

Drone Principles, Systems, and Payloads

Within the last decade, the commercial drone industry has grown significantly as new devices are continually developed for emerging applications. Yet, in spite of the extensive range of shapes, sizes, payloads, and capabilities, generally, all UAV systems can be categorized as either fixed-wing or multirotor UAVs, with some exception (Wingtra 2019).

Fixed Wing

Fixed-wing UAVs most resemble traditional manned aircraft, as a fixed-wing drone typically includes a central body, single propeller, and two wings. Much alike manned aircraft, fixed-wing UAVs generate and maintain the aerodynamic force lift, as air flows over and beneath the surface of the wing or airfoil creating areas of low and high air pressure, respectively. As such, fixed-wing UAVs are controlled by the movement and positioning of the ailerons and rudder surfaces to control the roll, pitch, and yaw of the aircraft, though these control surfaces differ greatly among devices (Fahlstrom and Gleason 2012).

The main advantage of fixed-wing UAVs is their ability to achieve much greater flight times (i.e., over multiple hours), as fixed wings are able to cover much larger spaces with a lower power consumption in comparison with multirotors (Boon et al. 2017). However, similarly to manned aircraft, fixed-wing UAVs require space for landing and takeoff. Takeoff is generally achieved by throwing the aircraft or using a catapult-like system (Fahlstrom and Gleason 2012). Also, as fixed-wing UAVs rely upon airflow to maintain flight, they are unable to hover or yaw on the spot. Because of this limitation, fixed wings rely upon banking turns that require a large operating space, making them difficult to maneuver in confined spaces.

Multirotor

As multirotor UAVs make up the majority of the commercial market and consumer models, they are the most common type of drone used by commercial operators as well as hobbyists and researchers. In contrast to fixed-wing UAVs, multirotors generate and maintain stable flight through the rotation of paired counterrotating propellers. Although a multirotor is defined as anything with two or more rotors, generally, the most popular configurations are quadcopters (four propellers), hexacopters (six propellers), and octocopters (eight propellers) (Fahlstrom and Gleason 2012).

Unlike fixed-wing UAVs, multirotors can achieve vertical takeoff and landing (VTOL) and are able to hover and yaw on the spot. This type of maneuverability makes multirotors commonly favored in congested or confined spaces (Castillo et al. 2017), particularly for filming or surveillance applications (see chapter ▶ "Investigations: Accidents and Reconstructions"). However, in comparison with fixed-wing UAVs, multirotors are much more power intensive, with flight times typically lasting under an hour on one battery.

Components

Although the airframes and control surfaces of multirotors and fixed-wing UAVs differ significantly, many of the internal components are identical and merely configured to suit the airframe and purpose of the aircraft. As such, fixed-wing and multirotor UAVs generally both include flight controllers (FCs), electronic speed controllers (ESCs), and brushless direct current (BLDC) motors and propellers, as well as a lithium-polymer (Lipo) battery/batteries to power the aircraft and a receiver (Rx) usually paired to a handheld transmitter (Tx) for piloting and controlling the aircraft (Quan 2017). The FC acts as the central brain of the aircraft for movement, control, and feedback. FCs are essential for receiving user commands and converting them into control

movements, as well as providing feedback from the aircraft using integrated onboard sensors, including accelerometers, gyroscopes, barometers, and magnetometers.

Also connected to the FC, ESCs receive a control command and convert this into a three-phase alternating current (AC) power, to power the BLDC motor and therefore spin the connected propeller. Depending on the configuration of the drone, the number of ESCs, motors, and propellers will differ; for example, a quadcopter will have four ESCs, motors, and propellers. A fixed wing may only have one single ESC, motor, and propeller, allowing the ailerons and rudder to be controlled by additional servo motors mounted on the aircraft (Fahlstrom and Gleason 2012). In addition, the FC may be a central hub for additional peripheral sensors, including a global positioning system (GPS) unit, typically used for flight stability, positional control and as a pilot aid. Or a number of other sensors used for object collision avoidance (i.e., ultrasonic, infrared, or stereovision cameras) or as additional pilot aids, for example, laser emitting diode (LED) lights, buzzers, and speakers.

Operation

Much alike the extensive variety of UAV devices, the setup and operation of these systems is equally varied. Although these systems may be controlled with something as simple as an app on a phone, most professional UAVs use either a traditional handheld Tx, with access to a range of flight modes with varying levels of pilot assistance, or a computer-based ground station. This is generally more common when controlling fixed-wing UAVs as these systems are generally used to conduct waypoint flying (a semiautonomous flight mode where an aircraft is pre-programmed with a sequence of GPS locations (ArduPilot 2019b)). Some systems, such as research-based systems, are controlled via an onboard computer, but these UAVs are beyond the scope of this entry.

To further aid the pilot, most UAV systems (i.e., DJI and Pixhawk) will have a LED indicator present to inform the pilot of the current status of the UAV while it is powered. These LED indicators will commonly flash different colors at different rates to inform the pilot of the current flight mode selected, whether the system has established a GPS lock (of a number of satellites as predetermined depending on the configuration of the device) or whether fail-safe is enabled, as well as being an indicator for any other potential errors, for example, battery warning and compass calibration (ArduPilot 2019a). Hence, it is therefore essential that any UAV pilot be aware of the LED indicator sequence relevant to their device as these differ significantly among models and manufacturers.

However, in the event of an emergency, the majority of UAVs come with pre-programmed fail-safes which are configured by the user during setup. Fail-safes, sometimes otherwise referred to as return to home (RTH) or return to land (RTL), are generally engaged by either the pilot in the event of an emergency, by a spotter in the case of pilot incapacitation or by the hardware during a loss of signal (DJI 2019a). As such, commercial Tx controllers usually come with a pre-programmed RTL fail-safe switches (on custom systems fail-safe switches can be selected by the user on programmable controllers (FrSky 2019)). Depending on the setup and control methods of the UAV, once engaged fail-safe programs will either attempt to return the drone to its initial takeoff positon (as determined from GPS data) or slowly descend to land in the positon that the switch was engaged in the case of multirotors or attempt a controlled descent in the case of fixed wings.

Payloads

As the value of UAV technology has been recognized within many applications, specific UAV payloads are being continually developed to meet the increasing application demands. With regard to this, many sensors are now custom developed for UAV use. For all UAV technology, weight is a significant consideration for flight time and power consumption. As such, advanced manufacturing capabilities allow UAVs to carry all manner of electronic and optical devices previously only suited to large and expensive manned aircraft.

The complete range of payloads available for UAVs is extensive and beyond the scope of this entry. Therefore, only the most popular payloads commonly integrated or attached to commercial drones with relevance to emergency and security management have been included.

Digital Cameras. Typical red-green-blue (RGB) digital cameras are the most prevalent integrated or added UAV payload on fixed wings and multirotors, as they are used for photography, digitization, and reconstruction of environments (see chapter ▶ "Investigations: Accidents and Reconstructions"). The range of digital cameras available for UAVs is extensive, and devices differ greatly in resolution, cost, and weight. Drone-mounted digital cameras extend the reach of the operator allowing a new perspective of a scenario (E. M. Robinson 2016). With regard to law enforcement, this may be for surveillance or tactical support, whereas in the criminal realm, a live feed from a UAV-mounted digital camera may provide as navigation tool when smuggling drugs into a prison.

Thermal Cameras. Thermal cameras are without doubt one of the most commonly integrated payloads on current commercial systems alongside typical RGB digital cameras. For emergency first responders and law enforcement, UAV-mounted thermal cameras are increasingly used to inform decision-making and provide situational awareness when tackling a large-scale building fire or wildfire. Thermal cameras can allow operators to "see" through the smoke to better determine the location of the fire and more efficiently combat the blaze. In addition to this, these systems are also continually deployed with success when searching for a missing person, especially when searching for elderly vulnerable people often disorientated in rural areas at night.

Laser Scanners. Laser scanners or light detection and ranging (LiDAR) sensors are increasingly deployed on UAVs as a tool for 3D mapping and reconstruction (GeoSLAM 2019). Unlike camera systems, laser scanners are much better suited to map large-scale sites with improved range in comparison with camera alternative;, however, these systems are costly (usually in excess of $30,000) which has limited their uptake among law enforcement. Laser scanners are not usually integrated on commercial UAV systems unlike thermal and RGB cameras, and therefore many laser scanning systems demand specific custom UAVs for deployment.

In addition to these sensors, other popular UAV payloads include gas and temperature measurement sensors, multispectral cameras, and hyperspectral cameras. Some also have lights and speakers, as in the case of a DJI Mavic 2 Enterprise (DJI 2019b), for the purpose of communicating with an individual typically needed during a search-and-rescue mission. Consequently, UAVs may not only have one payload onboard; it is not uncommon to have both an RGB camera and a thermal camera as is the case on an Aeryon SkyRanger (Aeryon 2019) or DJI Mavic 2 Enterprise Dual (DJI 2019b). Also, in some cases, multiples of the same devices may also be used, such as when undertaking stereovision.

Criminal Drone Use and Threats to Security

All drones are designed with one of two purposes in mind, either to transport and deliver goods or as a vehicle for data capture using differing payloads and sensors. These examples, often used by businesses or law enforcement, are also true of criminal drones. The use of drone technology is currently emerging into the criminal world as cheaper commercial devices have become easier to access, modify, and use. As a result of this, over the last few years, there has been an escalation of criminal drone incidents and near-miss accidents by civilian users worldwide. The most notable criminal events include airport drone sightings, drone smuggling, potential assassination attempt, and illegal flying and illegal filming of large-scale events. Therefore, this section explores a number of incidents that have caused damage or threats to security, which in some cases have led to policy and procedural change.

Airport Sightings

Over recent years, there have been multiple drone sightings at airports all over the world. However,

mass disruption was caused at Gatwick (UK) Airport on the 19th–21st of December 2018 (BBC 2019). During this time, multiple drone sightings were reported to the police by 115 people as a drone was seen on different occasions close to the runway. Without proper procedure put into place to cope with this incident, approximately 1,000 flights were canceled or delayed as the runway was closed for a total of 33 h. Although to date, the culprit has never been caught despite extensive efforts by Sussex Police. Since this incident, Gatwick and a number of other British airports have deployed counter drone technology to cope with drone sightings better in the future. In addition to this, legislation was also altered as before this incident in the UK, there was a 1 km exclusion zone for drone use around airports without permission, which has been extended to 5 km since the event. Arguably, extending the exclusion zone may reduce the likeliness of drone sightings in the future, as a deterrent for illegal operators. However, the UAV pilot responsible for this incident was already flying within the previous 1 km exclusion zone.

Smuggling

Another example of criminal drone use that appears internationally is the use of UAV technology to smuggle drugs, phones, weapons, and other contraband into prisons. Typically these incidents involve common commercial UAV systems that have been modified to carry a desired payload of contraband into the prison (NBC News 2015). In the UK between 2016 and 2017, seven members of a gang were found to have flown £500,000 worth of drugs into prisons during 55 drone deliveries (BBC 2018a).

Assassination Attempt

During the speech of President Nicolás Maduro at a military parade in Venezuela on August 4, 2018, two drones were detonated in different locations in a possible assassination attempt of the President (BBC 2018b). Although arrests have been made, it is unclear who was behind this crime (see ▶ "Event Security" and see ▶ "Investigations: Criminal" in this encyclopedia). These systems much alike the ones outlined in section "Smuggling" appear to be modified commercial UAV systems set up to carry and detonate the explosive payloads.

Illegal Filming

In addition to these examples, other more common occurrences of illegal flying have included illegal filming of open-air area events, for example, sports events and festivals. Although the intentions of the pilot may not be malicious, overflying such a large group of people is illegal and is dangerous to the crowd in the event of a hardware failure.

Arguably, the majority of UAVs used by law enforcement and general commercial operators is likely to be reliable off-the-shelf commercial systems frequently assessed and favored for their robustness. In contrast, criminal UAVs are much more likely to be custom-built devices configured to meet the specific needs of the mission, such as a unique release mechanism for smuggling drugs (see section "Smuggling") or with the ability to remotely detonate a device as outlined in section "Assassination Attempt." With this in mind, a greater risk is generally associated with these devices than to commercially available ones as they are likely to be configured without expertise, typically using cheaper components.

In addition to the events outlined above, UAVs have been used illegally in many incidents both with and without malicious intent. For example, the use of weaponized or surveillance UAVs has been used by terror groups during acts of war overseas. Additionally, UAVs have been sighted overflying emergency events, causing a nuisance to first responders and law enforcement and potentially delaying aid being rendered to victims.

Drone Use in Law Enforcement

Much alike many other applications, UAV technology is having a profound effect upon police practice and procedure. Specially, UAVs are providing law enforcement with situational awareness and therefore offering the ability to provide an overhead view during criminal and terrorist incidents while supplying real-time information leading to an improvement in operational planning and

response, staff management, and risk assessment (see ▶ "Criminals: Terrorists" (environment, political, religious) and ▶ "Protection and security in public spaces" in this encyclopedia).

In an investigative context, aerial imagery has long been considered a valuable resource, as it can provide practitioners with aerial spatial information recorded at a specific time (Brilis et al. 2000). However, until recently, widespread access to aerial platforms by law enforcement has been limited, due to the high purchase price, operational cost, and maintenance associated with operating manned aircraft (e.g., helicopters). For this reason, the emergence of low-cost drone technology for law enforcement is providing aerial support to even the smallest departments (Robinson 2016). This is enabling many practitioners to access "real-time" remote sensing abilities, with the opportunity of rapidly overseeing large search areas using covert approaches (Pringle et al. 2012). Recent international events that have demonstrated the benefits of situational awareness provided by UAVs have included, but are not limited to, the surveying of a structure after a fire, such as the Grenfell Tower fire (London, UK) in June 2017 and the Notre Dame fire (Paris, France) in April 2019.

As such, the scope of UAV technology within law enforcement is extending rapidly as new applications are recognized daily. With this in mind, for completeness in this entry, other uses of UAV technology relevant to emergency and security management have been included although this is not an exhaustive list (West Yorkshire Police 2019; Wiltshire Police 2019):

- Searching for missing persons.
- Surveillance of VIP visits.
- Tactical operation support.
- Coordination of multiagency events.
- Crime scene recording.
- Crime scene reconstruction (see chapter ▶ "Investigations: Accidents and Reconstructions").
- Land surveying.

However, despite these overwhelmingly positive examples, law enforcement use of drones has been met with mixed reviews (Heen et al. 2017), with the majority of negative opinions regarding concerns with public privacy (Bentley 2018). Public perception of UAV use undoubtedly relies heavily on previous media coverage of UAV missions in the Middle East, as opposed to the use of small, commercial UAV systems popular among law enforcement. Unfortunately, adverse public perception of UAV use by law enforcement cannot be disregarded; instead, it has led to the development of legislation as discussed in the next section.

Drone Legislation and Public Perception

In an attempt to manage the recent surge of UAV pilots across the country, legislation has been introduced to provide guidelines and promote best practice among private, civil, and commercial users (see ▶ "Investigations: Criminal" in this encyclopedia). In the USA, the Federal Aviation Authority (FAA) regulates UAV use for hobbyists, commercial operators, and law enforcement for the purpose of ensuring a safe airspace for all users of manned and unmanned aircraft (FAA 2019c).

Currently, the legislation surrounding UAV use is continually evolving as new technologies and applications are providing a variety of challenges for policy makers. As such, an exhaustive review of drone legislation has not been included within this entry; however, very basic guidelines and legislation provided by the FAA have been included below for all UAV pilots (see FAA website, section "Getting Started"; FAA 2019b):

- Register your drone.
- Fly your drone at or below 400 f.
- Keep your drone within your line of sight.
- Be aware of FAA Airspace Restrictions.
- Respect privacy.
- Never fly near other aircraft, especially near airports.
- Never fly over groups of people, public events, or stadiums full of people.
- Never fly near emergencies such as fires or hurricane recovery efforts.

- Never fly under the influence of drugs or alcohol (FAA 2019b).

Further information and up-to-date guidance and legislation can be found on the FAA website for all UAV users, with an additional section available with extra resources for public safety and government users (FAA 2019a). It is, however, important to remember that these rules differ internationally and when wishing to fly a UAV abroad, it is essential to check the UAV laws in that country.

With regard to legislation, a crucial factor is being confident that the flight can be safely made, although this conclusion involves a general understanding of the flying area with regard to hazards and proximities to airfields. When operating a UAV safely, knowledge of the aircraft is also crucial, and this includes both the airworthiness of the device and the pilot's knowledge of controls, flight modes, flight times, and operating capabilities (i.e., wind speed, GPS).

In spite of the FAA legislation, it is not the role of the FAA to police or manage illegal UAV flying, but solely to provide legislation to ensure a safe and consistently managed airspace for all users across the country. As such, it is the responsibility of law enforcement to manage this activity and investigate where appropriate. With regard to this, the FAA has provided a number of resources to support law enforcement when tackling and handling illegal drone use.

Conclusion

To summarize, current law enforcement operations have shown a positive trend of police drone use despite public concerns regarding privacy. Because of these promising examples, it is likely that law enforcement drone use will further increase as legislation becomes clear and cohesive. However, as this entry highlights, the proliferation of drone use among law enforcement has also occurred within the criminal realm leading to breaches in security, damage, and frequently reported incidents "6 in 2014, 29 in 2015, and 70 in 2016" (Department for Transport 2017, p. 6). Because of this, increased planning and policies should be put in place to counteract rouge drones especially in security threat scenarios such as the Gatwick Airport (UK) drone incident in 2018.

Definition

The following discussion addresses issues in school safety and security inclusive of strategies such as risk assessments and risk management principles that apply to safety and security concerns for educational institutions.

Introduction

These principles should provide the foundation for planning and prevention efforts at schools throughout the nation. Merriam Webster (2019) defines security as "the quality or state of being secure: such as freedom from danger: SAFETY, or freedom from fear or anxiety." When discussing the topic of security at educational institutions, the term security is typically accompanied with the word safety as observed in Webster's definition, since safety and security coexist in the development of plans, prevention efforts, and response actions designed to keep people and property safe. The phrase school safety and security will be used to describe protective efforts being used on school campuses inclusive of buildings, sporting and other events, arenas, and other locations and properties used and controlled by educational institutions.

Recognizing the Importance of School Safety, Security, and Preparedness

Educational institutions have the responsibility to protect the physical and psychological well-being of their students and staff. This includes the creation of positive school climates, preventing negative behaviors such as bullying and harassment, and being prepared to respond to threats such as weather emergencies, fires, and acts of violence. Effective crisis planning, prevention, response, and recovery strategies are essential for schools to meet this responsibility (Cowan et al. 2013). Currently there are over 98,000 schools in the United States providing education to students ranging from kindergarten through 12th grade (K-12) and over 7,000 institutions of higher education (NCES 2018). Although officials proclaim that protecting our nation's schools and their campus populations

L. R. Shapiro, M.-H. Maras (eds.), *Encyclopedia of Security and Emergency Management*,
https://doi.org/10.1007/978-3-319-70488-3

is a priority and that significant improvements have been made towards the enhancement of safety and security, some locations simply go through the motions of preparedness. While the majority of schools report the existence of plans and policies to deal with school safety and security (NCES 2018), some schools still lack the level of effective planning and preparedness measures necessary to ensure students and staff are adequately prepared (NSBA 2017). Institutions of higher learning appear to be even less engaged in campus safety and security efforts than K-12 schools with training and lockdown drills, fire drills, and other protective measures less common. The reality is that too many campuses are grossly unprepared, and in some cases these institutions even engage in activities counterproductive to safety and security. Justifications for refusing to take protective security measures include the perception that measures create an invasion in privacy or the appearance of a prisonlike environment, and although a balance between physical and psychological security needs to exist (NASP 2013), basic security measures must be established.

Framework for Success

To be successful in the creation of a safe and secure climate, educational institutions must establish and reinforce interdisciplinary, collaborative, and cohesive approaches to safety and security supported by appropriate funding sources. The involvement of behavioral and mental health professionals, safety and security personnel, teachers and staff, other support groups, programs, and services, and the community itself must be integrated into an overall multitiered approach to ensure school safety and security is established and maintained. Educational professionals, including the American School Counselor Association, National Association of School Psychologists, National Association of Elementary School Principals, National Association of Secondary School Principals, National Association of School Resource Officers, and the School Work Association of America, agree that effective school safety and security efforts require the following:

- Executive level buy-in and proactive leadership
- The ability of educational leaders to utilize human and financial resources in a manner that best meets the needs of their school and community
- Providing a team-based framework to facilitate effective coordination of services and interventions
- Balancing the needs for physical and psychological safety
- Employing properly trained school mental health and safety professionals
- Providing relevant and ongoing professional development for all staff
- Integrating a continuum of mental health support within a multitiered system of supports
- Engaging families and community providers as meaningful partners
- Remaining grounded in the mission and purpose of schools: Teaching and learning (Cowan et al. 2013, p. 3)

School safety and security is dependent upon the successful integration of school safety and crisis management principles. This development and implementation of efforts should involve multiple phases and strategies focused upon preparedness, prevention, mitigation, response, and recovery efforts. Additionally a multi-hazard threat identification process, multi-hazard planning, and multi-agency support and response strategies should be utilized.

Personnel Involvement and Development of Strategies

Some believe the greatest risk to school safety and security could be the lack of effective strategies to address prevalent problems (Timm 2014). Security plans must focus on efforts to reduce risk, prevent loss, and prepare for emergencies. Although it is imperative that schools are prepared for active shooter/mass murder events, the preoccupation with these events may have taken away from the focus on other more prevalent threats to educational institutions and their students and

staff. Administrators must actively and continually engage in the identification and prioritization of key threats to their campuses and ensure that, at a minimum, the following basic measures are taken:

- Establish school safety and security practices and policies:

  Do not wait until an incident occurs. Identify potential risk exposures or vulnerabilities. Develop, document, and disseminate corresponding practices and policies. Train and drill staff and students, based on those policies and established response procedures.
- Continually monitor the school's culture and climate while identifying security needs:

  Identify your schools culture and climate as well as threats, issues, and stressors your students are exposed to, and routinely update to meet changes.
- Constantly improve upon efforts to prevent violence, sexual assault, bullying, harassment, and other issues:

  Schools must implement methods to identify victims and obtain information on perpetrators before issues become wide spread. Strategies should be continually improved upon to reduce violations while increasing the frequency of reporting by students and staff.
- Foster respect, develop quality relationships, and promote the importance of safety and security:

  Establishing a safe and secure educational environment is essential for the creation of an atmosphere that is conducive to learning. Safety and security personnel must be recognized as a vital part of school campus, and the establishment of quality relationships must be developed. By demonstrating mutual respect between school administrators, teachers, security personnel, and students, the foundation of these relationships can flourish creating an environment where information about potential threats to school safety and security will be shared.
- Educate staff, students, and response personnel; people are the most important part of any safety plan:

  Security measures are essential; however they can be inconvenient. Open communications and the establishment of a campus wide clear understanding of security concepts are needed. Improvements in the understanding of security procedures by staff members and age-appropriate students and their need to maintain situational awareness will not only improve upon the importance of safety and security, but also improve the ability to detect potential threats and strengthen defensive measures against those threats. Awareness improves preparedness and minimizes risk.
- Review, adapt, and update emergency procedures:

  Establish the ongoing practice of evaluating current threats, existing emergency plans, and prevention and response capabilities. This not only identifies flaws and weaknesses but also results in changes and improvements in safety and security efforts. Evaluations and updates are a never-ending cycle (Timm 2014, para. 3).

Success additionally requires the development of partnerships and the establishment of coordinated response efforts with mental health professionals, local law enforcement, EMS, other first responders, and the community itself. Fortunately, many institutions of higher learning have made considerable progress in coordinating response efforts with local responders; however, the critical need for involvement in continual training and the incorporation of drills with faculty, staff, and students is often lacking. This lack of training is problematic because individuals not only need to know what to do in emergency situations but also possess the mental and physical ability to perform the activities needed. This level of preparedness requires training where personnel physically practice the desired response procedures. These activities will increase the ability of individuals to effectively perform the desired responses during high-stress situations, when an individual's cognitive thought processes are significantly diminished. Proper preparation is essential to success.

Goal of Educational Safety and Security

Ultimately, the goal of all educational institutions should be to establish an enhanced level of security and preparedness while maintaining a positive learning environment. The question is: How can schools protect themselves from acts of violence, crimes, disasters, and other situations which can be harmful to students and staff and disruptive to education? No single solution exists, and approaches will vary between locations; however, the answer can best be found in a holistic, multifaceted approach that utilizes layers of security supported by effective procedures and situational awareness. Efforts must additionally include the state of individual preparedness.

Security in Layers

Effective security requires a layered approach incorporating the use of teachers and staff in primary and auxiliary security roles while employing multiple physical and physiological impediments for deterring, denying, and delaying entry or unapproved access of individuals and other threats. This holds true regardless of the type of man-made threat, whether it is a cyber threat, a thief, a sexual predator, or an armed intruder. Although deterring or preventing attacks is the primary goal, auxiliary goals include delaying intruders long enough to allow detection, response, and apprehension, thus preventing them from reaching their target or minimizing the negative impact. Potentially beneficial impediments include signs, presence of personnel, lights, locks, sensors and alarms, fences, walls, security doors, security glass, bollards, and large planters. Natural barriers such as rivers, lakes, mountains, cliffs, ditches, mature trees, and even dense vegetation can also be effective for creating physical and/or physiological security barriers. Generally speaking the more layers of effective security, the better the result.

Since it is impossible to make a location or asset completely secure, a common strategy in security, often referred to as target hardening, involves expanding the use of protective measures to enhance security and decrease the criminal's chance of success or perceived chance. Creating a location that appears to be more secure than similar locations enhances security efforts and theoretically deters the adversary from attacking the more secure site in favor of another less secure location where the attack is more likely to succeed.

Effective Use of Technology

The use of technology to identify potential threats can be crucial. For example, cyberattacks may go undetected for substantial periods of time, and individuals in active shooter incidents are often initially unaware of the attack. Shot sensors with automated notification systems can be an effective solution for ensuring occupants and law enforcement are quickly notified about active shooter situations. This technology is additionally capable of providing accurate locations of gunfire and continual updates to authorities.

Other technologies include intrusion resistant doors, windows, bullet-resistant glass/panels, and automated locking mechanisms which can quickly lock doors creating barriers and denying access or mitigating the impact of violence to potential victims. The use of closed circuit television (CCTV) enhanced with threat detection software can improve the identification of suspicious activity and unauthorized entry. The use of hard rooms which are bullet and intrusion resistant and equipped with CCTV monitors and unpublished communications lines allows occupants the ability to establish and maintain communications with first responders, security personnel, and others in the school. Another potentially beneficial technology is software that allows officials to scan social media for potential threats/concerns associated with cyber bullying, suicidal discussions, threats of violence, or other harmful activities. The software flags troublesome posts that can be reviewed by preselected officers and/or school officials trained to identify language associated with likely threats. Although this technology can be controversial, by explaining the intentions of the search, the fact that only public communications are examined, and the narrow focus of the search, concerns can be reduced.

Prevention

The ultimate goal of safety and security is to avoid the loss of life and property through the prevention or interruption of actions before they cause harm. To effectively accomplish this, one must first identify potential threats. Critical information about threats to schools often comes from within the school itself or the greater community. Obtaining information about impending threats can be challenging and is often dependent on the development of trust between individuals before information will be shared. This trust is best achieved by fostering positive relationships between officials, students, and the community at large. After information concerning potential threats is obtained, it can be evaluated and prioritized through the use of risk assessments/threat assessments. These risk assessments, along with the use of emergency management and security principles, can be effective in the development of strategies to prevent or reduce harmful activities.

Deterrence

Deterrence is a desirable outcome that can be achieved by making a location appear so secure from attack or other unlawful activities that a successful attempt seems unlikely or significantly less likely than at another more vulnerable location. Even though no single solution exists for all locations, successful security programs should incorporate the use of multiple physical and physiological impediments to aid in the identification and deterrence of individuals, vehicles, and other threats.

Deny or Delay Access

Although budgets, school culture and climate, and even the physical locations themselves and their surroundings will impact what can incorporated into protective measures, one should consider the use of beneficial impediments such as security personnel, lights, fences, walls, protective bollards, large decorative planters, and natural barriers. By denying or even delaying access, security can improve its ability to detect adversaries and prevent the infliction of harm or at least mitigate the negative consequences of the breach regardless if the attempt involves a cyber threat or an armed intruder. If the threat involves active shooters or other violent individuals, the act of simply closing and locking the doors of classrooms during instructional periods is an effective and often simple means of denying or delaying access to students and staff. There have not been any successful breaches by active shooters into classrooms with securely locked doors.

Identifying and Preparing for Threats

School safety is a relatively new area of study that has been brought to the forefront by repeated cases of violence, including active shooter situations (Borum et al. 2010; Cornell and Mayer 2010). The ensuing rise in media coverage and public concern has resulted in significant changes in school discipline and school safety measures throughout the nation (Borum et al. 2010). In reality, the percentages of violence-related deaths occurring at schools are extremely small, while the frequency in victimizations of students and staff at schools is considerable.

The Centers for Disease Control and Prevention (CDC) stated that homicide is the second leading cause of death among youth aged 5–18; however, only between 1% and 2% of these deaths happened on school grounds or on the way to or from school (2018). The CDC further reported that between 1992 and 2015, the number of homicides of students 5–18 years old at schools or coming to and from schools averaged 22.8 per year, and the number of suicides averaged 5.9 (2018). However, the *Indicators of School Crime and Safety Report* provided by the National Center for Education Statistics (NCES) stated that during the 2015–2016 school year, 79% of public schools recorded one or more incidents of violence, theft, or other crimes had taken place, amounting to 1.4 million crimes (2018). During the same school year, 47% of schools reported one or more of the crimes to the police, resulting in a total of 449,000 crimes. Ten percent of public school teachers reported being threatened with injury by a student from their school, and 6% reported that a student from their school had physically attacked them. In 2015, approximately 3% of students aged 12–18 reported that they were afraid of being attacked or harmed at

school during the school year and 22% of students in grades 9–12 reported that illegal drugs were made available to them on school property (NCES 2018). The report further indicated that many of these crimes were not reported to law enforcement including serious violent crimes, where only half of the cases were reported to police. Serious violent crimes included "rape, sexual assault other than rape, physical attack or fight with a weapon, threat of physical attack with a weapon, and robbery with or without a weapon" (NCES 2018, p. 55).

Risk Management and Risk Assessments

Schools and universities must identify, evaluate, and prioritize their threats and associated risks and then develop effective strategies to manage those risks. This process should begin with the use of risk management strategies and include the incorporation of risk assessments. The Department of Homeland Security defines risk management as "the process for identifying, analyzing, and communicating risk and accepting, avoiding, transferring, or controlling it to an acceptable level considering associated costs and benefits of any actions taken" (2013, p. 7). Although one typically thinks of security in relation to man-made threats against persons or property, security personnel are involved in the prevention, mitigation, preparation, response, and recovery efforts for all threats, man-made and natural regardless of the cause. Risk management is intended to enhance the overall decision-making process, increase the ability to achieve objectives, and shape and control risk.

Although risk management cannot identify or eliminate all risk through the incorporation of risk assessments, the process can prioritize the risk identified and guide safety and security efforts towards the threats and associated vulnerabilities that are most likely to result in significant harm. This process will allow schools, federal, state, and local officials the ability to identify, develop, and employ approaches that are effective in preventing or mitigating future incidents. Risk management additionally incorporates the use of sound organizational practices such as planning, preparedness, program evaluation, and process improvement while considering existing budgetary restraints. According to DHS (2013), the key principles for effective risk management include:

1. Unity of Effort: Risk management is an enterprise-wide process and should promote integration and synchronization with entities that share responsibility for managing risks.
2. Transparency: Risk management depends on open and direct communications.
3. Adaptability: Risk management actions, strategies, and processes should remain dynamic and responsive to change.
4. Practicality: Risk management cannot eliminate all uncertainty nor is it reasonable to expect it to identify all risks and their likelihood and consequences.
5. Customization: Risk management programs should be tailored to match the needs and culture of the organization while maintaining balance with the specific decision environment they support (pp. 11, 12).

Risk Management Process

In an effort to ensure uniform, systematic and interoperable approaches to risk management, DHS encourages the use of a standardized process. Standardization improves the ability of different agencies and entities to work effectively together while possessing a shared understanding of information, analysis, and an improved and informed decision-making process. One should keep the aforementioned risk management principles in mind when implementing the risk management process.

The DHS risk management process includes:

1. Defining and framing the context of decisions and related goals and objectives
2. Identifying the risks associated with the goals and objectives
3. Analyzing and assessing the identified risks
4. Developing alternative actions for managing the risks and creating opportunities and analyzing the costs and benefits of those alternatives

5. Making a decision among alternatives and implementing that decision
6. Monitoring the implemented decision and comparing observed and expected effects to help influence subsequent risk management alternatives and decision (2013, pp. 15–25)

To develop effective strategies, officials must examine realistic threats while also taking into consideration the individual school and property, surrounding environment, and the school's climate and culture. This should be accomplished through the use of risk assessments and/or school assessments.

Risk Assessments and the Development of Site-Specific Strategies

Most educational institutions have experienced substantial cuts in budgets, and all institutions have finite resources. A critical element in the creation of a safe and secure environment for educational facilities and campuses is the identification and prioritization of threats and associated risk. This can be effectively accomplished through the use of assessments typically referred to as risk assessments. Risk assessments allow officials to prioritize potential threats, illegal, or harmful activities by considering the likelihood of events occurring in association with the negative consequences that would result if they did occur.

There are numerous methodologies that have been used to evaluate risk. These methodologies significantly range in complexity from the basic risk matrix developed by the Department of Homeland Security in 2007 ($R = T \times V \times C$) which evaluates risk through the examination of threats, existing vulnerabilities, and the resulting consequences to more complex models that expand upon the CARVER matrix, which historically was used by US Special Forces for mission planning. The CARVER matrix examines the areas of Criticality, Accessibility, Recuperability, Vulnerability, Effect, and Recognizability to evaluate risk. There are also methodologies designed to focus on one specific threat area such as the *Operational Guide for Preventing Targeted School Violence* published by the United States Secret Service in cooperation with the US Department of Homeland Security.

It is important to identify a risk assessment methodology that meets the needs of the institution but does not exceed the capabilities of the assessors, information available, or other resources needed. Assessments should not be conducted by a single individual or randomly chosen personnel. Assessments should be completed by a team of carefully selected assessors from multiple backgrounds and disciplines that are applicable to the needs of the assessment. For example, it would be appropriate for an assessment focused on school violence to include carefully selected educational professionals (teachers, councilors, administrators, etc.), law enforcement, behavioral and mental health professionals, social services, and other disciplines/entities (NASP 2017). Team members should also receive appropriate training prior to conducting the assessments.

Common Threats to Schools, Universities, and Their Associated Campuses

When examining the existence of threats and associated risk, there are obviously varying factors and concerns impacting educational institutions such as the age of the students, size and population of the campus, physical structure and design of buildings and public spaces, assets present, existing security measures, and even external threats associated with the region. Regional and local variables for consideration include population density, crime rates, visibility of school, ease of access, regional weather associated threats, or even exposure to potential external threats such as chemicals or other harmful materials located in nearby plants or being transported on highways or railways. Exposure to pandemics and other public health hazards must be considered along with a host of other external and internal threats. Even the type of educational institution significantly impacts safety and security measures. Many of the issues facing high school students are not prevalent in the lower elementary grades, for example, the use of illegal drugs in high schools versus grade schools. Logically this results in differences in the strategies and use of resources for combating illegal drug in the two types of schools. The National Center for

Education Statistics reported that only 5.9% of public grade schools conducted random sweeps using drug detection dogs, while 62.3% of public high schools used these tactics (NCES 2018).

Middle schools and university campuses certainly have their own priorities as well, resulting in varying approaches. Although differences in prioritization of threats exist between institutions, there are also common concerns that many institutions share. Examples include bullying and cyberbullying; physical and sexual assault/abuse; verbal and other communicated threats; possession of weapons, drugs, alcohol, or other prohibited items; theft, criminal mischief, and other property crimes; cyber intrusions; fire; threats from nature such as tornados, hurricanes, winter storms, floods, tsunamis, and earthquakes; pandemics and the spread of disease; mental health issues; and even litigation. One of the most common concerns addressed is violence or the threat of violence, including the statistically small but devastating threat of active shooters/mass murders.

Active Shooters/Mass Murders

There are various attack methods that have been used in active shooter/mass murder events including firearms, knives or other cutting instruments, blunt striking weapons, explosives, and even vehicles. The type of weapons, funding available, and a host of other variables, can impact the measures used by schools against such weapons, and schools must carefully take these factors into account when developing plans and protective measures. If a school is attempting to prevent vehicles from gaining access to areas on campus frequently used by pedestrians, the use of trees, ditches, walls, bollards, and large planters could be an effective and unobtrusive tactic. However, shortfalls in funding can make these measures cost prohibitive to implement throughout the entire campus. Therefore planners should consider identifying areas commonly associated with dense populations and make those locations the priority for implementation of these protective measures.

If the goal is to keep potential attackers out of a classroom, educational institutions can replace existing doors with doors that are capable of being automatically and remotely locked or update existing doors with automated door locks. Although it is an expensive improvement, especially when a school is updating all doors, it would enable doors to be locked without delay when an armed intruder was detected and a lockdown was initiated. However, another simple, less costly, and potentially more effective means to reduce risk would involve not waiting until a lock down was called to secure and lock classroom doors but to manually close and lock classroom doors at the beginning of each class and keep them locked until the instructional period is over. By closing and locking classroom doors during instructional periods, the level of risk will be effectively reduced and safety significantly improved. This simple tactic would effectively minimize or eliminate existing shortcomings resulting from delays in notifications and the time and danger involved for teachers attempting to reach, close, and lock their doors. This method will additionally negate the issues stemming from a teacher's inability to lock doors because of their loss of cognitive thought and diminished fine motor skills resulting from exposure to extreme stress. This approach obviously depends on the ability for rooms to be locked while still allowing students to exit in the event of a fire or other emergency requiring evacuation. In situations where evacuation is warranted, hallways should be briefly checked for threats before students exit the classroom and before students enter adjoining hallways.

Although this is a simple and effective tactic, many educators remain reluctant to incorporate these types of tactics claiming it is too disruptive to open doors for late students. Such excuses are not acceptable. If educators are not physically capable of opening the door for latecomers, assistants or age appropriate able-bodied students can be used. Educators should additionally keep classroom keys in their possession at all times and/or memorize codes for entry in the event a door becomes locked, and they need to reenter the classroom. Doors which are either unable to be locked and secured or which will not allow

students to exit when the door is locked should be replaced or updated with the appropriate hardware. If all educational institutions that have fallen victim to active shooter attacks had effectively implemented and practiced the policy of closing and locking doors during class periods and checking hallways before evacuations, the number of lives saved would have been significant. The Sandy Hook Advisory Commission reported that there has never been an active shooter who successfully breached and entered a closed and locked classroom door.

Participants in Preparedness

In reality, everyone has a role in enhancing their security by maintaining situational awareness of their surroundings and through the development of personal response plans (mental rehearsals). Personal response plans should outline primary and alternate plans of action in the event an active shooter or other critical incident occurs. Response plans should include options such as immediate and rapid evacuation of the threat area, involving the identification of primary and secondary escape routes prior to the emergency. An alternate tactic in active shooter situations should involve remaining out of sight, preferably in a secure area that provides barriers capable of stopping gunfire, should be considered. A last resort response in active shooter/mass murder situations may involve the aggressive use of force against the assailant. This defensive tactic can include the use of improvised weapons such as fire extinguishers to disorient attackers and/or the use other available items to physically assault the attacker. As another last means of defense, age and physically capable groups that are sheltered within a room or other area can develop coordinated response plans that involve the use aggressive physical force to protect themselves in the event an assailant gains entry into their area. These plans should include identifying specific duties/tasks for each of the key defenders and a coordinated overall plan of action. Each member should mentally rehearse and prepare for their duties. These aggressive tactics are certainly dangerous but a better option for physically capable individuals than relying on the hope that they will be spared.

Conclusion

Clearly the involvement and participation of faculty, staff, and students are essential to success. However, the incorporation of security engineering and protective design along with the development and implementation of effective plans, policies, and procedures is also essential. Training is another key component and should include the initial and ongoing instruction of personnel while also considering the use of age and situational appropriate activities that reinforce and engrain concepts introduced in training. The use of drills and scenarios can be effective in improving personnel's ability to perform tasks while under stress, when their cognitive thought process is significantly diminished. Success is also dependent upon the establishment of partnerships including the development of coordinated response efforts with local law enforcement and other first responders. Each of these actions is not possible without the support of administration and key officials, making administrative buy-in essential to success.

The process may sound complicated, but in reality it is a logical progression for any safety and security professional. Being prepared will save lives in active shooter situations and other critical incidents, and local law enforcement and other emergency responders can be an excellent resource for the development of safety and security measures. Ultimately it is the responsibility of educational institutions to provide a safe environment that is conducive to learning. To effectively achieve this, teachers, students, and staff must become involved in safety and security efforts and knowledgeable about response strategies and their respective roles. Personnel and age-appropriate students must maintain situational awareness and should develop personal plans (mental rehearsals) outlining primary and alternate plans of action they will take in the event of an active shooter or other critical incident. These steps will

reduce hesitation to act, which can be fatal during critical incidents. Personal action plans should include options such as the immediate evacuation of the threat area or remaining out of sight, preferably in a secure area that provides cover capable of stopping gunfire. Mental preparation should additionally include consideration for the use of aggressive force against the shooter. It is also critical for students, parents, school personnel, and the community to challenge educational institutions that are not properly prepared. Lives may depend on it.

Definition

Emergency management is defined as the process which involves the ability to mitigate, prepare for, respond to, and recover from emergencies, crises, and/or disasters.

Introduction

Since the beginning of recorded history, disasters have occurred, and there is no person, community, or organization immune to the adverse impacts of disasters. Unfortunately, when disasters occur, there is a general lack of proper preparedness, response, and recovery actions and capabilities, even when the hazards are chronic and frequent. When a natural disaster does occur, people, communities, and organizations respond vigorously to address the negative impacts caused by the event. Additionally, the hope is that the same vigor displayed during a response to an emergency is also evident during lessons learned meetings to help reduce the possible damage from any future disasters. Research has shown that immediately following recovery from a disaster, there is a sense of normalcy, translating into a sharp increase in thoughts and

behaviors *away* from the disaster event. The notion that we have "survived" takes over, and any ill feelings about the disaster subside. Disasters affect people, communities, and organizations in many different and adverse ways.

People, communities, and organizations must remain steadfast in the various phases of emergency management to allow for the best possible outcome regarding any future disasters. The range and variety of emergencies that could potentially involve emergency management is quite extensive. It is, therefore, undeniable and essential that emergency management is an integral part of daily lives. Four phases or functions of emergency management exist: preparedness, response, recovery, and mitigation. This chapter focuses on describing emergency management best practices and providing examples within each four phases or functions of emergency management.

Emergency Management: Preparedness

Emergency management preparedness is defined as a continuous cycle of planning, organizing, training, equipping, exercising, evaluating, and taking corrective action regarding disasters. A critical element within emergency management preparedness is the development of an emergency management response or action plan. As with every response or action plan, the plan is only as good as the degree by which it is reviewed, approved, tested, and communicated.

Preparedness also entails performing the required degree of due diligence regarding the understanding of the threat landscape. This aspect of preparedness is essential as it places focus on those threats which are most prevalent and assists with the development and refinement of the emergency management response or action plan. Preparedness also focuses on preparing for both natural and human-made disasters.

Emergency management preparedness measures provide a heightened standard or "pre-disaster" awareness and structure from catastrophe. The risk of injury, loss of life, or damage of operational capabilities is limited with proper emergency management, crisis communication, business continuity, and evacuation plans. Primarily, emergency management preparedness focuses on the needed readiness to respond to all-hazards incidents and emergencies. Because emergency and disaster events can occur without notice, people, communities, and organizations engage in emergency management preparedness to help establish an enhanced state of readiness to facilitate response. Emergency management preparedness best practices include, but are not limited to:

- Mandating and conducting, at a minimum, annual emergency management plan testing, review, and update, or whenever there has been a change in the organization that can impact the plan (e.g., significant staffing changes, changes in services offered, etc.). Akin to conducting fire and evacuation drills, mandating and executing the testing of emergency management plans is an essential component of practicing sound emergency management and a best practice.
- Coordinating and conducting testing and reviews of emergency management plans with external entities (e.g., local first responder organizations, regional organizations, and other company locations and facilities) that are critical to the ongoing operation of the organization. Whether human-made or natural, disasters can cause catastrophic damage; therefore, partnering with critical external entities pre-disaster has proven to serve as a fundamental best practice.
- Periodically conducting awareness training activities that helps ingrain preparedness within the culture of the home, community, and organization. Research has shown that people, communities, and organizations that regularly conduct awareness training activities are more prepared for responding to disasters. In addition to awareness activities, it is also a best practice to periodically coordinate scheduled awareness training in coordination with regularly scheduled plan testing efforts. A best practice would be to conduct

awareness training as part of the regular emergency management plan review and testing initiatives.
- Adopting an all-hazards risk management approach by conducting an organizational hazard identification and risk assessment allowing organizations to identify their vulnerabilities concerning managing disaster and emergencies. It is essential for people, communities, and organizations to not only perform risk assessments for natural disasters like severe weather but also to practice sound risk management with an all-hazards approach (e.g., including both natural and human-made disasters).
- Instructing emergency management personnel to complete training in the use of the Incident Command System (ICS). The ICS encompasses a standard approach to emergency management and can significantly enhance emergency management response by identifying a defined set of roles and responsibilities. Disasters inherently can be complicated to respond to, because of different factors and impacts which can change rapidly. When there is a framework already defined, established, and tested regarding roles and responsibilities, emergency managers are better prepared to address the twists and turns that complex disasters can bring.
- Including processes and protocols which address communication in emergency management preparedness. The magnitude and importance of clear, accurate, and timely communication within emergency management cannot be understated. A critical best practice is to create a communication plan which includes establishing protocols for notifying family members, members of the community, and individuals within the organization, prior, during, and after disaster and emergencies. The emergency management communication plan helps establish external communication processes to allow a family, community, and organization to keep abreast of response to disasters and emergencies.
- Addressing additional emergency-related strategies, including shelter-in-place, evacuation, fire drill, and lockdown plans, and reviewing and testing them periodically.
- Establishing mutual aid/assistance agreements with external stakeholders. This best practice is one that has successfully been implemented and well documented during large-scale disaster events like Hurricane Katrina and Superstorm Sandy. A crucial task within preparedness is to conduct periodic reviews and update mutual aid/assistance agreements as required.
- Incorporating infants and young children, as well as pets, in emergency management planning activities. The welfare of infants and young children, as well as pets, is an essential component of emergency management preparedness and often overlooked (see ▶ "Emergency Management: Infant and Young Children Feeding in Emergencies" chapters in this volume).

Emergency Management: Response

Emergency management response entails how people, communities, and organizations react to crises and disaster events. The emergency management response phase encompasses the coordination and deployment of resources to address the crisis or disaster to minimize harmful impacts. Emergency management response best practices include, but are not limited to:

- Utilizing the ICS framework and capability during the response phase. The ICS framework significantly enhances response by providing a defined structure regarding roles and responsibilities during emergency response.
- Utilizing and leveraging the established communication plan created as part of preparedness activities during the response to an emergency.
- Adopting, testing, and integrating an emergency notification system (ENS) or mass

notification system (MNS). An ENS or MNS is defined as a tool or application which sends one-way messages to inform the public of an emergency. Organizations best served by an ENS or MNS include fire and local law enforcement; emergency management organizations; federal, state, and local governments; cities and communities; and building owners, building management companies, and businesses that can justify its need and investment. ENS and MNS significantly improve the safety and security of an organization by providing alerts and real-time instruction during an emergency or disaster. ENS and MNS have been in existence for a brief number of years and are commonplace within academic institutions. These systems are often also referred to as "reverse 911" communication systems.

- Utilizing pre-established emergency operations center (EOC) process, plan, and capability. While not a viable option for individuals or families, the implementation of an EOC enables communities and organizations to respond effectively to large-scale disasters.

Best Practices: Emergency Management – Recovery

The emergency management recovery phase consists of those activities that continue beyond the emergency management response phase to manage stabilization efforts. "Recovery involves providing immediate support during the early post-disaster period necessary to return vital life-support systems to minimum operational levels and continuing to provide support until the community returns to normal" (Petak 1985).

Although recovery is a distinct phase in the life cycle of emergency management, activities that take place during other phases can affect the recovery phase.

The recovery phase begins immediately after the threat to human life has subsided. The goal of the recovery phase is to bring the affected area back to some degree of normalcy (see also ► "Emergency Management: Recovery" in this volume). Emergency management recovery best practices include, but are not limited to:

- Engaging in research concerning financial funding from disaster relief sources and organizations. Disaster relief sources and organizations exist to provide needed assistance and relief during the recovery phase.
- Establishing travel and lodging agreements near recovery locations. Among the four emergency management phases, it is the recovery phase that inherently has the most extended duration, as the impacts from a disaster may require reconstruction of buildings, roads, and infrastructure, which takes time to complete. By establishing travel and lodging agreements ahead of an emergency, employees are in a better position to focus efforts on recovery operations.
- Engaging human resources within the organization's emergency management plan to allow the department to assist during the recovery phase. Establishing employee safety and travel kits and creating cash accounts with debit cards are excellent best practices regarding emergency management recovery activities.
- Engaging the community at large in establishing partnerships before disaster events.

Best Practices: Emergency Management – Mitigation

Emergency management mitigation is an effort to reduce the loss of life and property by lessening the impact of disasters and emergencies. Mitigation involves structural and non-structural measures taken to limit the effects of disasters and emergencies. Emergency management mitigation actions, involving physical structures, include changing the characteristics of buildings or the environment. Examples would consist of flood control projects, raising building

elevations, and clearing areas around structures. Emergency management non-structural components would entail adopting or changing building codes. Overall, the importance and interest in conducting hazard mitigation have grown recently in response to the increase in both the frequency and severity of natural and human-made disasters, which unfortunately have resulted in the loss of life and property and economic losses. Hazard mitigation is "any action taken to reduce or eliminate the long-term risk to human life and property from hazards. The term is sometimes used in a stricter sense to mean cost-effective measures to reduce the potential for damage to a facility or facilities from a disaster event" (FEMA 1996). Emergency management mitigation best practices include, but are not limited to:

- Initiating hazard mitigation activities at the city, local, and community level, where land-use decisions are made, as well as construction codes and standards adopted and enforced. Also, hazard mitigation efforts at the community level provide an opportunity for community leaders to incorporate hazard mitigation into their decision-making processes (see also ▶ "Natural Hazards" in this volume).
- Incorporating hazard mitigation techniques into decisions. Hazard mitigation can be as simple as conducting periodic tree trimming near company facilities and homes. This mitigation best practice can ensure that severe weather events that may cause tree branches to snap would not impact power lines or homes from damage. As a best practice, promoting and investing in hazard mitigation efforts is a direct way that families, businesses, and communities can reduce human and economic losses from future disasters.
- Expanding the ability to minimize the impact of a future emergency or disaster. This best practice was tested and implemented during global pandemic fears in recent years.
- Collaborating and partnering with an organization's jurisdiction to create mitigation plans that address the community's unique risks, reduce vulnerabilities, and enhance community resilience. Collaboration efforts also enable a community to maintain a "local perspective" to the mitigation plan and create "community buy-in." Taking the collaboration best practice a step further, it is also essential to consider developing a collaborative planning approach. The approach encompasses establishing a multi-jurisdictional planning team, pooling resources, and expertise from the community, using in-house staff, and effectively involving the public in hazard mitigation planning.
- Taking advantage of funding through grants. These funding sources can be used in hazard mitigation efforts and activities.
- Including counter-terrorism awareness and training which is a modern-day best practice and can significantly minimize or mitigate the impacts of future domestic terrorist attacks (see also ▶ "Terrorism: Domestic" in this volume).
- Implementing a comprehensive cybersecurity policy to help mitigate the impacts of future cyberattacks (see also ▶ "Cybersecurity: Policy" in this volume).

Conclusion

There is no doubt that disasters will continue to be a part of human existence, causing adverse impacts on people, communities, and organizations throughout history. Over time both human-made and natural disasters have caused devastation in the form of loss of life, severe property damage, substantial financial ruin, and destruction to critical infrastructure. The discipline of emergency management provides a comprehensive approach to management efforts before, during, and after disasters occur. It provides the framework and structure to enhance the ability of people, communities, and organizations to address disasters and continues to evolve with changes in hazards, technology, and the environment. The four foundational phases or functions of emergency management include preparedness,

response, recovery, and mitigation. Each emergency management phase differs concerning scope, objectives, and purpose, but together all four aspects work to address the management of disasters. The different phases of emergency management, while each independent, work along a continuum or cycle. Unfortunately, some people, communities, and organizations do not implement emergency management best practices. These best practices have been identified and shared to benefit people, communities, and organizations alike. Those who implement emergency management best practices significantly enhance their ability to address future human-made and natural disasters.

Definition

A crisis situation is "a major occurrence with a potentially negative outcome affecting the organization, company, or industry, as well as its publics, products, services, or good name" (Fearn-Banks 2016, p. 1).

Crisis communication can be specified as "the collection, processing, and dissemination of information required to address a crisis situation" (Coombs 2010, p. 20).

Introduction

In recent years, crisis communication has become one of the major areas of interest in crisis management literature. Authors agree that it is impossible to manage a crisis adequately without including communication in the crisis management process. Crises or threats for crises

create an environment where information is needed. Numerous researchers explored various crisis response strategies depending on the nature of crisis and the crisis phase. This major interest has created an abundant amount of information for experts working on crisis management practices (Coombs 2010).

It is almost impossible to list all possible crises for organizations. Events such as explosions, activist actions, rumors, fire, earthquakes, death, product harm, terrorism, and strikes are threats that could evolve in a crisis situation (Coombs 2007). Although these crises occur in various forms, numerous authors have developed crisis typologies based on overlapping characteristics (Mitroff et al. 1996; Lerbinger 1997). Coombs (2007) synthesized these typologies into 11 crisis types: operational disruptions from disasters, workplace violence, rumors, unexpected loss of key leadership, malevolence, challenges, technical-error accidents, technical-error product harm, human-error accidents, human-error product harm, and organizational misdeeds.

While communication has often been seen as the most efficient way to improve the management of these crisis, two communication strategies, risk communication and crisis communication, have tended to focus on different stages in the crisis management cycle. Traditionally associated with public health and emergency management traditions, it is the aim of risk communication to inform people about potential harm in order to encourage them to take action to mitigate the risk. Risk management holds the assumption that the public has the right to know possible dangers. Transparency about potential harm allows people to make informed choices regarding risk (Seeger 2006). While risk messages mainly emerge before a crisis situation occurs, crisis communication, which has its roots in crisis management and public relations, focuses on communication during and after an event. Communicators are focused on the actions that must be done in order to resolve or contain the crisis by spreading well-timed, accurate, and useful information. Despite the differences between these types of communication, they are both part of the larger business continuity management plans of an organization (Coombs 2010).

Theoretical Frameworks in Crisis Communication

Several theoretical frameworks have been developed for the understanding of communication processes and results in crisis situations. While some researchers rely on related disciplines such as sociology, psychology, and rhetoric, several studies make a contribution to crisis communication research by applying public relations theories. For example, according to the contingency theory of strategic conflict management (Cameron et al. 2007), various contingency factors can affect the communication between the organization and the public. The theory seeks to select the most appropriate crisis response depending on the threat level of the crisis. Crisis communicators can draw on the issue management theory (Ulmer et al. 2007) when attempting to understand the public perceptions and attitudes toward an organization during a crisis event. Grunig's (Grunig 1997) situational theory of publics defines that various specific factors can be identified in the responses of the public toward an organization in a crisis situation. The theory explains how people communicate and when communication aimed at the public is most effective depending on the phase of the crisis event. The apologia theory of Fearn-Banks (2016) focusses on defending the organization's reputation and protecting the image after the organization has been accused of a misdeed. Aside from a real apology, the theory includes denial, explanation, and expressing sorrow as crisis communication strategies. Building on the apologia theory, the image restoration theory (Benoit 1995), or later referred to as the image repair theory, identifies two components of an attack to the image of an organization: the attacked person or organization is responsible for the action and the action has to be considered offensive. The perception of the crisis is fundamental to image restoration. Benoit (1995) identifies five possible response strategies: (1) denial, when the organization denies that the act occurred; (2) evading responsibility, which can contain provocation, defeasibility, making excuses, and suggesting the action was justified based on good intentions; (3) reducing

offensiveness, when the organization attempts to reduce the negative feelings experienced by the audience; (4) corrective action, when the organization claims that the problem will be corrected; and (5) mortification, when the organization admits responsibility and asks for forgiveness.

Today, the more recent situational crisis communication theory (SCCT) of Coombs (2007) accounts for the majority of studies on crisis communication management. It has its roots in Weiner's attribution theory (1985) and presents an overview of different response strategies to specific crises. Similar to the image repair theory, Coombs emphasizes on the responsibility of the crisis and the impact of communication on the general perception of the action. More important than the actions itself is the perception of the crisis (Benoit 1995; Coombs 2007). Depending on the responsibility of the organization, three clusters of crises are categorized: (1) victim crises, such as terrorism or natural disasters where the organization has little or no responsibility; (2) accident crises, such as technical errors, where the organization can be partly held responsible; and (3) intentional crises, such as fraud, where the organization could have prevented the crisis. Possible response strategies involve the denial of the crisis, the diminish of the crisis or the focus on rebuilding the relationship with the stakeholders, including bolstering as secondary response strategies.

The dominant crisis communication theories above do not address how social media can be used in crisis management. Although the use of social media during crisis events has become a vibrant and rapidly growing interest of researchers in recent years. To establish a framework for the use of social media as a crisis communication tool, the social-mediated crisis communication model (SMCC) (Jin et al. 2011) was developed. According to this model, three key publics transmit crisis information: (1) influential social media creators who create social media messages, (2) social media followers who consume the information spread by the social media creators, and (3) social media inactives who may consume crisis information indirectly via mouth-of-mouth communication or traditional media. Organizations have to take into account five factors (crisis type, crisis origin, organizational infrastructure, crisis message source, and crisis message form) when communicating about the crisis. Depending on those factors, different perceptions of the messages by the intended public can be explained (Jin et al. 2011).

Communication Within the Three Phases of Crisis Management

In order to approach the crisis in an effective way, communication starts long before an event occurs and continues after the immediate threat has receded. In literature, authors identified three phases of a crisis situation: pre-crisis, crisis and post-crisis. In the pre-crisis phase, or the developmental stage, conditions which can lead to a crisis accumulate. When the primary impact of a crisis event is experienced, the crisis stage is reached. A triggering event, such as an accident, outlines the start of this phase. The post-crisis phase is characterized by recovery and self-assessment which may reveal future opportunities or negative effects (Meyer and Reniers 2016). The length of each phase depends merely on the complexity of the situation, the emerged issues, and the time needed for resolution (Ray 1999).

All crisis phases, from the pre-crisis prevention period to the actual crisis and post-crisis containment, must be covered by specific communication strategies. A variety of types of crisis communication can be identified depending on the phase of the event (Coombs 2010). Equally for all crisis phases, the involvement of a broad number of stakeholders is recognized. This implies that any individual or group who receives an impact of the achievement of the organization's objectives has to be included in the crisis communication management (Ulmer et al. 2007). Based on the work of Coombs (2010), specific types of communication can be identified depending on the crisis phase. Below we outline these types.

Pre-crisis Phase

In the pre-crisis phase, the crisis communication plan includes preventive measures that reduce the

known risks that could potentially lead to a crisis situation and presents an overview of the preparatory activities for management during the crisis. At this moment, information required to address a crisis situation has to be collected, decisions about how to manage potential crises have to be made, and people who will be involved in the management process of the crisis have to be trained. Communicators have the responsibility to create awareness about potential crises in order to encourage the public to be heedful for possible crisis sources. As it is a challenge to not normally accept the changes or anomalies as regular or innocent, pre-crisis communication is focused on the identification of risks or irregular signals and the education of the public about the preparation for a crisis situation (Seeger 2006).

Crisis Phase

During the crisis, communication is crucial since it has a significant effect on the outcome of the crisis. During the event, information needed by the crisis team is collected and processed, and messages to people outside of the crisis team are created and disseminated. The crisis response guidelines for messages toward the public highlight three focal characteristics: quickness, accurateness, and consistency. First, the initial response has to be provided immediately after the crisis situation occurred. It is important that the responsible crisis communicator has the possibility to tell his side of the story before the media or other relevant actors start sharing their often inaccurate information. Second, messages have to be updated regularly in order to focus on sharing only accurate information with the outside world. Third, crisis communication has to be consistent. A recommended communication strategy is the appointment of a crisis team that shares the same information with the responsible communicators in order to maintain accuracy (Coombs 2010).

Post-crisis Phase

In post-crisis phase, communicators stop focusing on managing the crisis itself but concentrate on the effects of the situation. If during the event communicators promised to share specific information afterward, this is the moment of delivering on that promise. Breaking the promise could result in the public losing their trust in the capacity of handling future emergency situations. Additionally, communicators share available information about the recovery process, corrective actions, or results of investigations of the crisis. The quantity of messages depends on the promised information during the event and the length of the post-crisis phase. Finally, post-crisis stage provides an opportunity to evaluate the operations of the organization, including the circumstances that led to the crisis and the used crisis management strategy (Mitroff et al. 1996).

Best Practices in Crisis Communication

In order to support crisis professionals with creating a communication plan adapted to the crisis phases, researchers of the National Center for Food Protection and Defense (NCFPD), a US Department of Homeland Security Center of Excellence, created a list of best practices in crisis communication based on evaluations of multiple case studies and an exhaustive review of literature about this topic (Seeger 2006). Numerous communication scholars and practitioners contributed to the compilation of the practices, which were published in a special issue on risk and crisis communication in the *Journal of Applied Communication Research* (2006). In later years, these best practices have been tested and expanded in several scientific publications (e.g., Sellnow et al. 2009; Veil and Ojeda 2010). In total, ten best practices were identified:

1. *The establishment of process approaches and policies*. While communication is often seen as an important factor after a risk or crisis occurred, the description of the different phases of a crisis event above already showed that communication should be involved in decisions before, during, and after an emergency situation. By integrating communication strategies in the decision process, communication issues can be solved more immediately and more fully in the planning and response phase of a crisis. Activities such

as the education of the public should be part of the ongoing policy of the preparedness for emergency situations.

2. *Pre-event planning*. In order to make the crisis management process effective, crisis planning and risk analysis are indispensable. Preventive actions such as the identification of potential threats, the calculation of needed resources, the synchronization of internal and external communication processes, and the assignment of responsibilities for team members make the approach of the crisis situation more efficient. Additionally, it is important that the crisis communication plan contains structures for regularly updates and revisions.
3. *Partnerships with the public*. Since the public has the right to know what risks it faces, they should be considered as a legitimate and equal partner in crisis management. During a crisis, it is the responsibility of the crisis team to share knowledge about the event with the public. The audience can, vice versa, also provide essential information that can be useful to mitigate the crisis. Thus, a dialogical approach between the public and the crisis management team is suggested.
4. *Attention for the public's concerns and understanding of the audience*. In order to create a dialogue between the public and the crisis team, it is important that the concerns of the public are taken into account regardless of whether the perceived risk is manifested. When positive relationships and a reservoir of goodwill are established before a crisis situation, the approach of a crisis event will be more successful.
5. *Honest, candor, and open communication*. By sharing information openly and honestly before, during, and after a crisis, the risk of reducing the trust of the public can be avoided. Once the public considers the organization no longer as a source of trustworthy information, the efficiency of crisis management is strongly reduced.
6. *Collaboration and coordination with credible sources*. In addition to the establishment of a strong dialogue with the public, the creation of strategic partnerships with credible sources is considered as a best practice. This network consists of reliable people who are indispensable for the coordination of crisis messages and activities. Authors emphasize the need of finding relevant partners at all levels and creating relationships before a crisis occurs.
7. *Meeting the needs of the media and remaining accessible*. In many cases, the media is the only source from which the public can gain information about the crisis situation. Meeting the needs of the media and remaining accessible is necessary in order to transfer the right messages. When communicating with the media, inconsistency should always be avoided. Therefore, media training for crisis managers and communicators should be part of the pre-crisis planning.
8. *Communication with compassion, concern, and empathy.* It is important that communicators react with compassion, concern, and empathy when referring to the crisis situation. Showing an expression of genuine concern and empathy convinces the public of the legitimacy and appropriateness of the proposed actions. Human reactions will always be better received.
9. *Acceptance of uncertainty and ambiguity.* Crisis situations always contain some level of uncertainty. Communicators could choose to wait until all relevant information is available before sending out messages. Hence, accepting uncertainty and ambiguity encourages the release of quick and truthful messages. A best practice is considered to acknowledge that the given information is still uncertain, for example, with statements as "we do not yet have all the facts." On the one hand, this allows the communicator to refine the message when more details about the crisis situation become clear, while on the other hand, statements that are likely to be shown as inaccurate are avoided.
10. *Messages of self-efficacy.* Messages that contain suggestions about what people could do to reduce the harm promote self-efficacy. The content of these messages depend on the nature of the event and can differ from avoiding certain products to donating in

order to help others. It is important that the public understands why a certain action is suggested and considered as meaningful.

Sellnow and Vidoloff (2009) added an eleventh best practice to the list of the NCFPD: the acknowledgement and account for cultural differences. It is important that those who do have a limited access to mainstream media still got informed about the crisis situation. Communicators should include the use of specific channels to reach underrepresented populations in their communication plan.

Based on these guidelines, communication professionals can improve their communication management plan. The eleven best practices are the principles or processes forming the basis of an effective crisis communication approach. It is important to mention that those best practices often complement each other and function together. As every crisis is a unique event that can evolve in very different directions, the establishment of a well-integrated and situation-specific approach is suggested (Seeger 2006).

Incorporating Social Media in Crisis Communication

Recently, social networking technologies have become a new trend in crisis communication management. During all stages of crisis events, people make use of multiple communication channels to reduce uncertainty and to obtain a sense of personal control over the situation (Lin et al. 2016). Because its convenience and quick accessibility, the use of social media during crisis events is increasing. In emergency situations worldwide, they have generated both opportunities and concerns (Branicki and Agyei 2015).

Firstly, social media have the opportunity to inform a wide audience about their safety and prosperity in a very short time period. Updates about the crisis event can be shared and reshared within a couple of seconds, reaching millions of people (Veil et al. 2011). Secondly, by regarding social media as a crisis communication channel, a more direct and personal connection with the public can be set up. The community becomes part of the actual crisis communication response (Lin et al. 2016). Thirdly, it allows crisis teams to get real-time information from the audience. By using social media proactively, comprehensive information from observers can be collected directly. Individuals have the ability to become sources of information by sharing their opinions and experiences with others. It provides clarity about the publics crisis needs as concerns and questions can immediately be addressed (Branicki and Agyei 2015). Finally, social media can be used to get in contact with less reachable individuals. By implementing various social network technologies in the crisis communication plan, individuals who cannot be reached by mainstream media could be informed through social media about the crisis situation (Veil et al. 2011).

On the other hand, while social media facilitates the relationship with the public during the crisis event, it can increase the organization's vulnerability as it is almost impossible to control the high-speed spread of information through this medium. Therefore, crisis communicators should manifest receptiveness, integrity, and fair-mindedness to hold back the public from being convinced of less-reliable sources of information. In order to do so, communicators should share a considerable amount of information through social media before a crisis situation occurs to guarantee that information seekers could already identify the reliable sources. When doing so, they will consult the information sources they know and have confidence during the crisis situation (Lin et al. 2016). Subsequently, since anyone with a social media account has the ability to share information or give reactions on other messages, the possibility of the spread of misinformation increases. Therefore, it is important to monitor all crisis-related posts. When trusted sources are unable to provide enough information, other individuals can start rumoring because of the lack of information. The impact of this misinformation cannot be underestimated for the reputation and future of the organization (Lin et al. 2016). Finally, concerns are rising about the possible technology failures when using social media. It is important that the use of social media is fully integrated in the crisis management and approaches. This implies that social media

technologies have to be tested and that evolvements in this field have to be followed up accurately in order to regularly update the crisis communication plan (Veil et al. 2011).

Despite these concerns, communicators almost have no choice in using social media as the public is already making use of it when informing each other about crises. In recent years, new media have acted as the main communication channel during crisis events. People are taking pictures or turn to the internet to get information and share opinions. If crisis communicators decide to narrow their focus on traditional media channels, conversations about the crisis will go on through social media without the organization's voice being heard. Importantly, literature shows that new and social media technology should not replace but complement the traditional communication channels (Schultz et al. 2011).

Conclusion

This article presented an up-to-date overview of the available literature about crisis communication in emergency and crisis situations. The overview has shown that the topic has been of great interest of numerous researchers. With the emerging use of social media, new opportunities and concerns have risen. In the future, more new emerging technologies in crisis management such as drones or virtual reality could create interesting opportunities and carefulness. As most relevant crisis communication approaches and practices were presented, this overview could be used by crisis communicators when making their crisis management plan of business continuity plan more effective.

Emergency Management: Crisis Management and Response

Michael K. Lindell
Department of Urban Design and Planning, Institute for Hazards Mitigation Planning and Research, University of Washington, Seattle, WA, USA

Keywords
Emergency response functions · Incident Command System · Multiorganizational networks

Definition

A community crisis is a potentially overwhelming situation that requires an urgent response to avoid severe consequences that exceed a community's capability to absorb. Often its cause, effects, and means of resolution are ambiguous (Pearson and Clair 1998) because of its unpredictability, speed of onset, and scope and duration of impacts (Perry 2018). These event characteristics produce a sense of uncertainty and urgency as households, organizations, and government agencies seek to rapidly mobilize and deploy available response resources.

Introduction

Community crises typically threaten both physical (casualties, damage to buildings, infrastructure, and agriculture) and social (psychosocial, sociodemographic, economic, and political) impacts (Lindell 2013, 2019; NRC 2006a). These potential impacts create agent-generated demands for actions to limit or avoid these impacts and response-generated demands for actions to coordinate all of the individuals and organizations that are responding to the agent-generated demands. Crisis response activities are conducted during a time period that begins with the detection of the event. In some cases, such as hurricanes, hazard monitoring systems (satellite detection coupled with computer-based atmospheric forecast models) ensure authorities are promptly alerted to hazard onset, so there is a long period of time to activate an emergency response organization. In other cases, such as earthquakes, preimpact prediction is usually not available, but prompt assessment of the impact area is feasible within a matter of minutes to hours. This allows emergency managers to direct search and rescue resources to extricate victims from collapsed structures. The crisis response ends when the situation is stabilized, which means that the risk of loss of life and property has returned to pre-crisis levels.

Emergency Response Functions

FEMA (1998, p. 12) described the goal of emergency response as "to save lives and property by positioning emergency equipment and supplies; evacuating potential victims; providing food, water, shelter and medical care to those in need; and restoring critical public services." More broadly, Lindell and Perry (1992) summarized emergency planning guidance in USNRC (1980)

and NRT (1987) in terms of four basic functions that emergency responders must perform in responding to disaster demands: emergency assessment, hazard operations, population protection, and incident management. These four functions provide a succinct way of describing what response organizations must do as they respond to an emergency. The purpose of *emergency assessment* is to define the nature and magnitude of the event by evaluating conditions in the physical and social environments. In the case of a hazardous materials transportation incident, this would involve identifying the types and quantities of chemicals involved, the current and forecast meteorological conditions that determine the direction and distance of exposure hazard, and the extent to which the population at risk has sheltered in-place or evacuated.

Hazard operations consist of preventive and corrective actions that limit either the likelihood or the magnitude of hazard impacts. These actions do so either by controlling the source (e.g., plugging leaks in hazmat containers) or by limiting hazard impacts (e.g., placing sandbags around structures threatened by floods). Hazard operations actions are preventive if they avoid a release to the environment. For example, spraying water on a tank car of chlorine that is next to a burning tank car of propane will prevent the chlorine from expanding and rupturing its tank (Noll and Hildebrand 2012). Hazard operations actions are corrective if they reduce the magnitude or terminate a release in progress (e.g., plugging a leaking tank car). Other hazard operations actions avoid property exposure by protecting or strengthening building envelopes (putting up shutters before a hurricane or shutting doors and windows and turning off HVAC systems before a toxic chemical release), securing building contents (e.g., in anticipation of earthquake aftershocks), or turning off utilities (to prevent escaping gas from being ignited by downed power lines).

Population protection actions range from the use of protective gear by responders to evacuations by community residents. The preferred method of population protection is to prevent people from being exposed to the hazard. This can be accomplished by initiating evacuation or sheltering in-place for people inside a hazard zone and access control to prevent people outside a hazard zone from entering it. If people have been exposed, emergency managers can reduce consequences such as the severity of injury or probability of death by conducting search and rescue operations to locate and extricate victims. Once this has been done, medical actions can be initiated such as first aid, transport to medical facilities, and definitive care.

Incident management ensures that emergency assessment, hazard operations, and population protection actions are undertaken in a timely and effective manner and that emergency responders have sufficient resources to do their jobs. In addition, it involves coordinating with other organizations to acquire additional resources and providing public information about the incident to people who do not need to take protective action.

As Table 1 indicates, the four basic functions have subfunctions that are similar to those that FEMA's (2010) CPG-101 recommends as functional annexes to the Basic Plan of a jurisdiction's Emergency Operations Plan (EOP). As the table indicates, FEMA's list of recommended functional annexes (which is more comprehensive than in earlier versions of this guidance such as DCPA 1978, and FEMA 1990) does not explicitly address emergency assessment or the initial activation of emergency response agencies, facilities, and equipment.

The interrelationships among these functions can be seen in Fig. 1, which Lindell et al. (2006) adapted from an earlier version in Lindell and Perry (1992). An emergency is defined by a *chain of events* beginning with an actual (or potential) release of energy or hazardous material that is currently being (or will in the near future be) transmitted through the environment to a community. The hazard agent acts together with community characteristics and environmental conditions to threaten exposures of persons and property (indicated by the solid lines). In turn, these exposures will produce physical (casualties, damage to buildings, infrastructure, and agriculture) and social (psychosocial, sociodemographic, economic, and political) impacts. To avoid these impacts, emergency managers use the information available at different stages of the chain of events

Emergency Management: Crisis Management and Response, Table 1 Typologies of emergency response functions (Adapted from Lindell et al. 2006)

Organizational functions	Organizational subfunctions	NRT-1 functions	CPG-101 local plan functional annexes	ICS sections
Emergency assessment				
	Threat detection/ emergency classification	Ongoing incident assessment		
	Hazard/ environmental monitoring	Ongoing incident assessment		Planning
	Population monitoring and assessment			
	Damage assessment		Damage assessment	Planning
Hazard operations				
	Hazard source control	Containment and cleanup	Firefighting; oil/hazmat response	Operations
	Protection works	Public works		Operations
	Building construction			
	Contents protection			
			Energy; agriculture and natural resources	
Population protection				
	Protective action selection		Population protection	
	Population warning	Warning systems and emergency public notification	Warning	
	Protective action implementation	Personal protection of citizens	Transportation	
	Impact zone access control/ security	Law enforcement	Public safety and security	
	Reception/care of victims	Human services	Mass care, emergency assistance, housing and human services	
	Search and rescue	Fire and rescue	Search and rescue	Operations
	Emergency medical care	Health and medical	Public health and medical services	
	Hazard exposure control	Response personnel safety	Worker safety and health	Command
Incident management				
	Agency notification/ mobilization	Initial notification of response agencies		

(continued)

Emergency Management: Crisis Management and Response, Table 1 (continued)

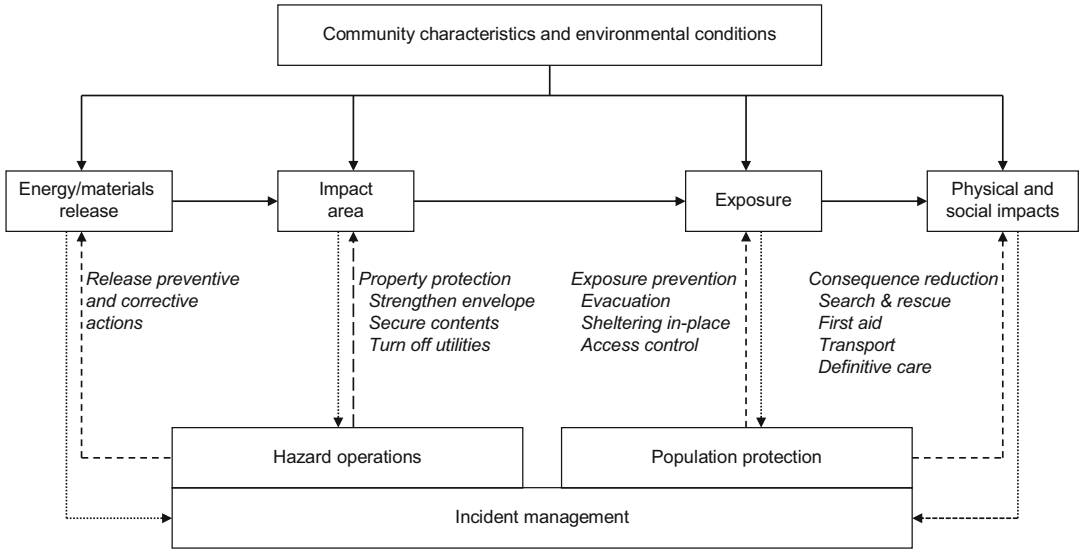
Organizational functions	Organizational subfunctions	NRT-1 functions	CPG-101 local plan functional annexes	ICS sections
	Mobilization of emergency facilities & equipment			Planning
	Communication/ documentation	Responder communications	Communications	All sections
	Analysis/ Planning			Planning
	Internal direction and control	Direction and control	Direction, control, and coordination	Command
	Public information	Public information/ Community relations	External affairs/emergency public information	Command
	Finance/ administration	Resource management	Financial management	Finance/ administration
	Logistics		Resource management; Logistics management and resource support; volunteer and donations management	Logistics
	External coordination	Direction and control	Mutual aid/multijurisdictional coordination; private sector coordination; long-term recovery	Command

to perform emergency assessment actions (indicated by the dotted lines) that allow them to assess the threat, impact area, exposure, and potential impacts. If incident managers can project future disaster demands (i.e., later stages in the chain of events) from current conditions, they can anticipate the tasks that will need to be performed at that later time (indicated by the dshed lines). In turn, this allows them to request additional resources and deploy them before they are needed rather than when it is too late.

Emergency Response Organizations

Effective incident management requires local emergency response organizations to rapidly mobilize human and material resources. This, in turn, requires a predetermined *concept of operations*, which is a summary statement of what emergency response functions are to be performed and how they are to be accomplished. In almost every case, this requires advance planning for coordination across a variety of local public sector, private sector, and nongovernmental organizations. It also requires a strategy for mobilizing extra-community resources and integrating them into the emergency response. Such coordination requires agreement about the emergency functions to be performed, as well as assignment of responsibility for emergency function performance to local and external organizations. In addition, the organizational structure must be defined in terms of the title and duties of each of the positions within the emergency response system and the reporting relationships among these positions.

Emergency response activities are usually accomplished through the efforts of diverse groups – some professional, others voluntary. In most rapid onset incidents such as earthquakes, the first people to respond are uninjured survivors in the impact area who begin the task of search and rescue. These volunteers are followed by local professionals such as police, firefighters, emergency medical services personnel, and public works employees. However, some components of the population protection function are assigned to other organizations. Mass care is usually



Emergency Management: Crisis Management and Response, Fig. 1 Chain of events model. (Adapted from Lindell et al. 2006)

assigned to the American Red Cross or Salvation Army, and evacuation support is often assigned to local transit authorities or school districts.

According to Dynes (1970), *established* organizations respond by performing their normal tasks with their normal staff, *extending* organizations perform new tasks with their normal staff, *expanding* organizations perform their normal tasks with new staff, and *emergent* organizations perform new tasks with new staff. When the agent-generated demands exceed the capacities of individual organizations, an *emergent multiorganizational network* (Drabek et al. 1981) forms to coordinate the response with the objective of achieving mutual goals as completely as possible with a minimum of performance gaps, unnecessary duplication, confusion, or conflict (Gillespie 1991). However, focusing on response-generated demands such as improvised coordinating mechanisms necessarily diverts valuable time from the performance of agent-generated demands such as search and rescue, so a *planned multiorganizational network* is a more effective way to achieve crisis management goals (Lutz and Lindell 2008).

Another response-generated demand is the acquisition of a wide variety of resources that are needed to ensure there will be an adequate emergency response. These resources include:

- *Trained staff* in sufficient numbers of personnel in each job title and their organization into cohesive response teams that have standardized titles and job descriptions so they can understand each other's capabilities and limitations,
- An *Emergency Operations Plan (EOP)*, *Standard Operating Procedures* (SOPs), and other job aids to guide emergency responders in performing tasks that are critical, infrequent, and difficult to perform,
- *Equipment* for emergency assessment (e.g., toxic gas monitoring devices), hazard operations (ranging from tank patching equipment to bulldozers and sandbags), population protection (ranging from respirators to traffic barricades), and incident management (e.g., computers, cell phones, and radios).
- *Facilities* such as incident command posts (ICPs), staging areas, incident bases, camps for emergency responders; jurisdictional

emergency operations centers (EOCs) to coordinate *inter*-agency activities, departmental operations centers (DOCs) to coordinate *intra*-agency activities, joint information centers (JICs), and congregate care centers ("public shelters") to house evacuees.

A major challenge is to ensure that each responding organization has timely access to the resources that it needs. In major disasters, this requires inventories of emergency response resources within the affected jurisdiction and adjacent jurisdictions, as well as preincident agreements authorizing the release of those resources, and effective communications procedures for requesting them during an incident.

The Incident Command System (ICS)

Southern California fire departments recognized the need for a common structure for emergency response organizations in the aftermath of their experience during the 1970 wildfires (Auf der Heide 1989). At that time, emergency responders were impeded by disparate organizational structures, inadequate emergency assessments, poorly coordinated planning, uncoordinated resource allocation, and inadequate inter-agency communications. This situation was consistent with the findings of five decades of research on organizational response to disasters, which repeatedly found that major disasters require coordinated response by many organizations. In many cases, much valuable time that should have been devoted to an incident's agent-generated demands was lost to its response-generated demands – trying to overcome differences in organizational design, positional titles, emergency response training, and organizational procedures (Drabek 1986; Lindell and Perry 1980; NRC 2006b).

The lack of standardization in the design of emergency response organizations was not an accident. For many years, the federal government provided state and local governments with criteria for evaluating their EOPs (DCPA 1978; FEMA 1990). However, it avoided requiring a specific structure for emergency response organizations. This resulted in a proliferation of organizational structures, positional titles, resource names, and operational procedures that impeded interjurisdictional cooperation – even among identical emergency response agencies (e.g., fire departments) from neighboring jurisdictions.

In the aftermath of the 1970 wildfires, Southern California firefighters developed a system that evolved into the Incident Command System, which was guided by a few basic principles (FEMA 2004). First, all jurisdictions use a common organizational structure defined by standardized names and functions for subunits and standardized names and duties for individual positions (standardization). Second, a division of labor assigns each unit a specific function to perform (functional specificity). Third, subunits are established to limit the number of personnel directly supervised by each unit manager (manageable span of control). This is usually five subordinates but can range from three to seven. Fourth, personnel from a given professional discipline, such as police or fire, are assigned to the same unit in the emergency response organization (unit integrity). This facilitates teamwork and also simplifies recordkeeping. Fifth, most incidents are managed by a single Incident Commander (IC) but a Unified Command (UC) team manages the emergency response when multiple agencies have statutory authority and responsibility for a specific type of incident. Sixth, emergency responders develop Incident Action Plans (IAPs) that include specific, measurable objectives and evaluate their effectiveness by monitoring the achievement of these objectives (management by objectives). Seventh, the IC or the UC team allocates all resources – personnel, facilities, vehicles, and equipment – to emergency response tasks (comprehensive resource management).

These features make the ICS a flexible structure for assembling resources and directing emergency response units that is adaptable to all types of hazards. Moreover, ICS can address large, complex, multijurisdictional incidents as effectively as very small, routine incidents. The modular organization of ICS allows an emergency

response organization's size and composition to change as the IC activates only those functional units needed to address current and projected incident demands. The Command Section oversees four sections – Planning, Operations, Logistics, and Finance/Administration – that are staffed as appropriate to incident conditions. Section chiefs work with Command staff to formulate an emergency response strategy and then direct tactical operations that are implemented by specialized branches within each of the four sections. In a fully implemented ICS, branches are established under sections to implement the tactical operations they have been assigned. Sectors are defined beneath branches and execute specific tasks. For large incidents, sections can be subdivided into geographic or functional branches which, in turn, are divided into geographical divisions or functional groups. Lower levels of organization include task forces comprising different resources and strike teams composed of a single type of resource.

In larger incidents, the Incident Commander is supported by a Safety Officer, a Public Information Officer (PIO), and a Liaison officer to coordinate with agencies such as law enforcement and the EOC. Within the ICS structure, Command delegates responsibility for implementing its emergency response strategy to the four section chiefs. The Operations Section deals directly with all hazard source control activities at the incident scene. These activities include terminating hazardous materials releases; suppressing fires; extricating, triaging, and transporting victims. The Planning Section is charged primarily with collecting, analyzing, and distributing incident data, forecasting resource demands, and other planning functions. The Logistics Section supports the emergency response organization by providing needed resources (e.g., facilities and equipment) and services (communications, information technology, medical). The Administration Section focuses on procurement, cost recovery, liability, and risk management.

After establishing an Incident Command Post to direct on-scene operations, the Incident Commander should follow the Emergency Operations Plan's concept of operations by assigning emergency response functions to the government agencies or other community organizations that are responsible for performing each of them. In addition, the emergency response organization should develop an IAP for each operational period that identifies the incident objectives, unit assignments, a communications plan, a medical plan, a safety plan, and other specialized plans or information, as needed. The IAP might be oral for a small incident but should utilize ICS forms to produce written documentation for major incidents. The IAP should be based upon situation reports (SITREPs) that describe the incident status and the resource status. SITREPs should address essential elements of information (EEIs) such as hazard information, incident boundaries, environmental information, and hazard impacts.

In any major emergency, the emergency response organization will need to maintain constant contact with the jurisdictional EOC, which will provide policy guidance and continuous technical assistance to responders at the incident scene. Such support includes obtaining weather forecasts, coordinating warning and evacuation, supervising mass care facilities, and disseminating public information. Moreover, an EOC is needed to request extra-community resources and to direct their disposition as they arrive from other local jurisdictions and higher levels of government.

Research on ICS Implementation

Although it seems logical to assume that implementing the basic principles of ICS will yield more effective incident management, there have been limited tests of this assumption. One line of evaluation has been to examine the merits of ICS on purely theoretical grounds or on the basis of anecdotal data (see Drabek and McEntire 2002, and Jensen and Thompson 2016, for reviews of articles of this type). For example, one early criticism of ICS was that it ignored the role of volunteers (Wenger et al. 1990), an issue that has been addressed is subsequent guidance (FEMA 2017). Moreover, as Table 1 indicates,

one disadvantage of ICS is that it largely ignores the population protection function, probably because these activities are usually performed away from the incident scene. Current versions of ICS must address these activities within the Operations Section or assume that they are being directed from the EOC, as was the case in Hurricane Rita (Lutz and Lindell 2008).

More generally, there is little empirical research on ICS effectiveness. A few studies have reported some degree of success in ICS implementation but noted that such success depends on each participating organization's extensive training and routine utilization of this system. Such high levels of training and utilization are feasible for organizations such as police, fire, and emergency medical services agencies whose missions to respond to routine emergencies. However, routine utilization of ICS is implausible for agencies such as Public Health and Social Services and even frequent training on ICS would be a significant burden on these organizations. Thus, even the limited research on ICS reveals limitations that need to be addressed; additional empirical tests of ICS effectiveness are needed to determine if there are other deficiencies (Boersma et al. 2014; Jensen and Thompson 2016).

Conclusions

The ICS's flexible structure can make three significant contributions to emergency response operations (Lindell et al. 2006). First, standardization can facilitate first responder training because training materials can be readily shared across jurisdictions. Second, ICS can increase the reliability of emergency response operations because its comprehensive structure can decrease the likelihood that important functions will be overlooked in the heat of emergency response. Third, ICS replaces *emergent multiorganizational networks* with *planned multiorganizational networks*. This avoids time delays associated with lengthy assessments of other response agencies' capabilities and the development of mutually agreed procedures. However, the fundamental basis of ICS is a set of management principles whose validity has been documented in research on *established* organizations that perform their normal tasks with their normal staff under modest levels of uncertainty and urgency. The unanswered question is whether these principles also apply to *extending*, *expanding*, and *emergent* organizations. Practitioner experience suggests that the *planned multiorganizational networks* established within ICS are superior to *emergent multiorganizational networks*. Nonetheless, there have been flaws found in ICS implementation. Consequently, further research is needed to assess ICS effectiveness in a wider range of conditions and identify modifications that can make it more effective.

Emergency Management: Evacuations

Michael K. Lindell
Department of Urban Design and Planning, Institute for Hazards Mitigation Planning and Research, University of Washington, Seattle, WA, USA

Keywords

Risk area · Evacuation route system (ERS) · Evacuation demand · Evacuation capacity · Contraflow · Phased evacuation · Evacuation re-entry

Definition

Evacuation is a process intended to temporarily move people from a hazardous location to a place of greater safety.

Introduction

This entry addresses vehicular evacuation from environmental hazards, but not pedestrian evacuation from buildings, aircraft, or ships because the scale and dynamics of these evacuations is quite different (Aguirre et al. 2011; Bolton 2007; Nelson and Mowrer 2002; Peacock et al. 2011). Moreover, the focus is on preimpact rather than postimpact evacuations because preimpact evacuations face the challenge of clearing the risk area before the beginning of hazard exposure (Cova et al. 2017).

Small-scale evacuations can be improvised by risk area residents without any coordination by authorities, as was the case in the American Samoa tsunami (Lindell et al. 2015). Large-scale evacuations take place surprisingly frequently; an evacuation involving 1000 people or more takes place every 2–3 weeks in the United States (Dotson and Jones 2005). Moreover, evacuations are effective; many people are removed from the threats of natural hazards such as floods, hurricanes, wildfires, and volcanic eruptions and of technological hazards such as explosions, toxic chemical spills, and radiological releases. Despite its frequency and success, however, evacuation is not an unquestionably appropriate response to all environmental hazards. For example, many tornadoes, toxic chemical releases, and radiological incidents have such a rapid onset and short duration that sheltering in-place would be more appropriate. Evacuation would also be inadvisable for people whose risk of movement exceeds the risk of sheltering in-place, as could be the case for intensive care patients (see *Emergency management: Sheltering in-place*).

The logistics of evacuation are relatively simple when authorities can provide adequate forewarning of a localized hazard in areas where households have their own cars and have friends or relatives to stay with until it is safe to return home. However, the challenges of evacuation management increase substantially with the size of the risk area and its population. Although the risk area for a small daytime release of many toxic gases is only about 1/2 mile downwind (USDOT 2008), other hazards involve much larger areas. A nighttime spill of a large quantity of methyl isocyanate has a downwind protective action distance of 7 miles or more (USDOT 2008), and a nuclear power plant accident might require an evacuation of the entire 10 mile emergency planning zone (EPZ) (McKenna 2000).

Contrary to some people's beliefs, even large scale evacuations are quite safe; the accident rate for private vehicles is almost certain to be no higher and is quite likely to be lower than during normal driving periods (Lindell and Perry 1992). This is because traffic flow tends to be slow, moving at about 35 mph and unidirectional (outbound), so collisions are less severe and, therefore, less likely to produce deaths or injuries or to severely obstruct traffic flow. Moreover, the available evidence on hospital and nursing home evacuation indicates that even mass evacuations of special susceptibility populations can be accomplished in short time periods without appreciable safety risks. There are, of course, important logistical barriers that must be overcome in order to assure that an evacuation is carried out in a timely and effective manner (Chenault et al. 1980).

The remainder of this entry is divided into three major sections. The first section covers preimpact activities involved in evacuation planning. The second section summarizes Lindell, Murray-Tuite, Wolshon, and Baker's (2018) comprehensive discussion of evacuation analysis – the activities associated with assessing the time required to evacuate a risk area and the points on the evacuation route system (ERS) where bottlenecks are most likely to occur. The third section addresses evacuation management – the activities involved in actually implementing an evacuation plan.

Evacuation Planning

Disaster researchers (Lindell 2012; Lindell et al. 2006) and evacuation planners (Houston 2009) agree that a critical first step in evacuation planning is to establish continuing contact among all of the organizations that will be involved in implementing an evacuation – especially emergency management, transportation, police and fire departments, social services, and the American Red Cross (or other shelter operators). In the case of regional evacuations, this includes the

affected organizations in other jurisdictions – counties or states – that will be involved in evacuation, shelter, and re-entry. As will be discussed below, an effective planning process will establish as coordinated response to the issues that need to be addressed in risk, transit, and host jurisdictions.

In addition, emergency managers should recognize that evacuation management, like any other emergency response activity, generally requires *improvisation* as well as *planning* (Kreps 1991; Mendonça and Wallace 2004, 2007). Improvisation is usually needed because the incidents that occur do not correspond exactly to the scenarios that guided plan development. Consequently, it is essential that emergency exercises be conducted so responders learn how to adjust to conditions that they did not expect and that all incidents involving evacuations be thoroughly critiqued to ensure that lessons are learned, plans and procedures are revised, and training is adapted for a better response to future incidents (see the entry on ► "Emergency Management: Crisis Management and Response").

Evacuation Analysis

Evacuation analysis is one component of population protection analysis which, in turn, is one element in community preparedness analysis (Lindell and Perry 2007). There are five steps in evacuation analysis. These are to (a) identify risk areas/sectors, (b) assess the size of the risk area population, (c) identify the evacuation route system (ERS) and assess its capacity, (d) forecast evacuation demand, and (e) model traffic behavior.

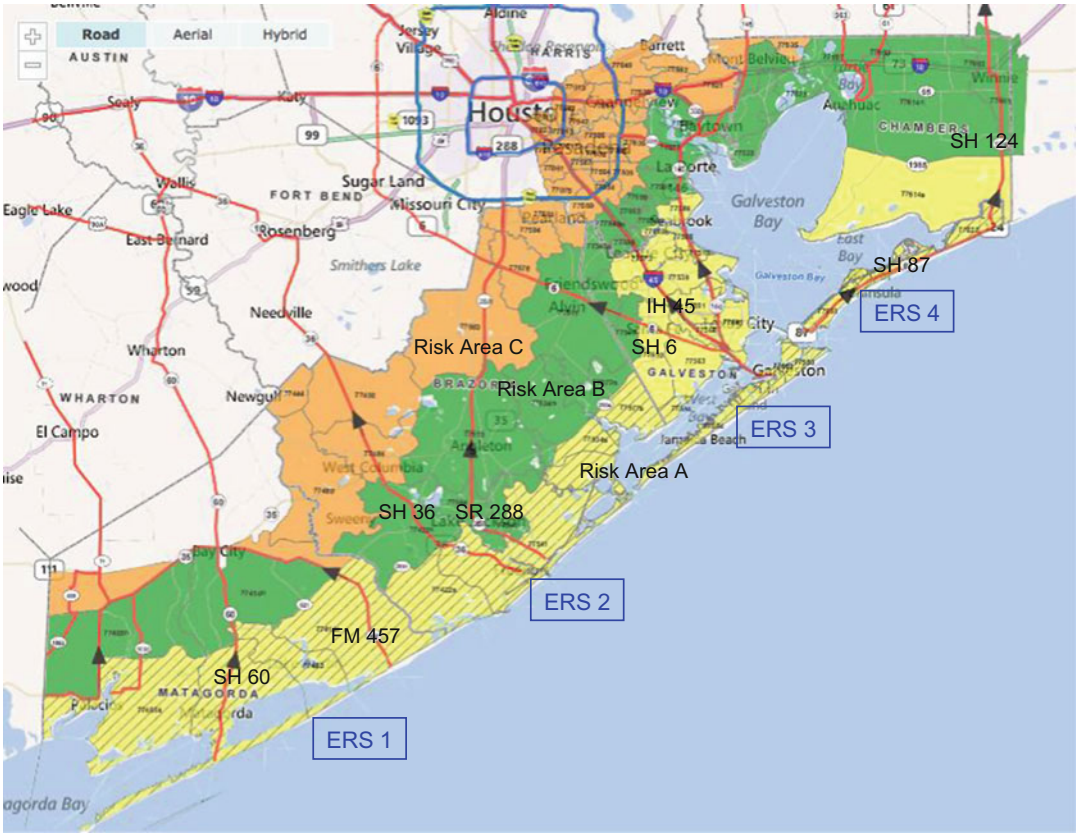
Identify Risk Areas/Sectors

A *risk area* comprises, as the name implies, the geographic areas at risk from a given hazard. For some hazards, equivalent terms are used such as a special flood hazard area (floods), vulnerable zone (VZ) (toxic chemicals), or EPZ (nuclear power plants). For most hydrometeorological and geological hazards, specialized agencies conduct risk analyses and provide risk area maps. However, identification of risk areas for hazardous materials is more difficult because the size of the risk area depends upon a number of factors, such as the quantity of material released, its volatility, toxicity (or radioactivity), and meteorological conditions such as wind speed, wind direction, and atmospheric stability. The USDOT (2008) provides simplified procedures for identifying risk areas for hazardous materials transportation, and the US Environmental Protection Agency (www.epa.gov/oem/tools.htm) provides procedures for fixed site facilities. There is a standardized 10-mile plume inhalation EPZ for all US commercial nuclear power plants (USNRC/FEMA 1980).

Whether for a natural (e.g., hurricane) or fixed-site technological (e.g., nuclear power plant) hazard, it is unlikely that all parts of an extremely large risk area will be advised to take the same protective action in an emergency. The most effective way to implement such protective actions is by identifying Emergency Response Planning Areas (ERPAs) – often called sectors in hurricane planning – that are areas of relatively homogeneous risk in which residents will all be advised to take the same protective action. Since these ERPAs or sectors should also be readily identifiable by those within them, emergency planners sometimes define them in terms of postal codes. This is necessary because many people have difficulty in identifying their location on risk area maps (Arlikatti et al. 2006; Zhang et al. 2004). Defining ERPAs by postal codes can work well in urban areas because postal codes in such areas are relatively compact (see Fig. 1). However, this can be problematic in rural areas if a single postal code covers a very large area having heterogeneous levels of risk. In such cases, ERPA boundaries can be defined by well-known political boundaries (city lines), geographical features (rivers), and major roads.

Assess the Size of the Risk Area Population

Vehicle-owning resident population. The basic unit of the vehicle-owning resident population is the household. The term *household* is important here because it is well documented that households tend to evacuate as a unit and will often seek to reunite if separated before evacuating (Tierney et al. 2001). The speed at which such households can evacuate thus depends on whether



Emergency Management: Evacuations, Fig. 1 Risk areas and the evacuation route system for the Houston/Galveston study area

members are united at the time of warning receipt, which is typical on evenings and weekends, and, if not, how soon they can reunite. However, there are times when households with multiple vehicles leave at different times after they have reunited (Maghelal et al. 2016). Moreover, depending upon the immediacy of the threat (usually minutes of forewarning for transportation accidents but days for hurricanes) and the potential for property destruction (low for toxic chemicals and high for hurricanes), people might take time to protect property (e.g., install storm shutters) or to pack valuables before evacuating. Most households have multiple members, which determines the required capacity of public shelters. In addition, most households have multiple vehicles and trailers, which increases the number of vehicles that need to be included in the estimates of evacuation demand.

Transit dependent population. The number of households without vehicles can be estimated by using data available from the National Household Travel Survey (nhts.ornl.gov/tools.shtml). Although the percentage of households without vehicles can be multiplied by the number of households in that area to estimate the number of households that will need public transit to evacuate, such estimates should be treated with caution. On one hand, some households have vehicles that are in poor repair and cannot provide reliable transportation over the long distances that are required for hurricane evacuations. On the other hand, some households that do not own vehicles are likely to obtain rides with other households that do. These two effects tend to cancel each other, but the relative magnitude of the two effects is unknown.

Transients. Transients can be individuals visiting the area on business or households

vacationing in the area. Transient populations can vary substantially by time of year, day of week (especially weekday vs. weekend), time of day, and also due to special events such as festivals and athletic events. Consequently, evacuation planners must be aware of this variation and incorporate it into their plans.

Special needs population. The special needs population comprises people with a variety of functional limitations in communication, medical health, functional independence, supervision, and transportation (FEMA 2010a, b; Kailes and Enders 2007). Some members of the special needs population are school children who must be evacuated directly to a safe location or who must be returned to their homes where they will evacuate with the other members of their households. Another important category of the special needs population is prisoners who must be evacuated under close supervision to another correctional institution – preferably before the rest of the risk area population begins to evacuate. A third major category in the special needs population comprises those who are institutionalized in hospitals, nursing homes, group homes, or other types of facilities (see Lindell et al. 2018, Table 3.3). Finally, 17% of the non-institutionalized US population has disabilities that substantially limit one or more of activities of daily living (Brault 2008). Thus, there is likely to be a significant fraction of the population in any risk area that will need some type of assistance when evacuating but whose location and specific needs are difficult to identify in advance. Mechanisms such as 2-1-1 calls are an important source of information for determining what types of vehicles will be needed and the types of facilities to which people with disabilities should be transported (Bame and Arlikatti 2019).

Time variation in ERPA population size. Evacuation analysts must recognize that the size of each population segment within each ERPA varies over time. There is variation by time of day as people travel to work, school, and other daytime activities and return home at night. This diurnal variation is most pronounced during the work week, but there can also be substantial variation by time of year in some communities, as tourists and people with second homes arrive in vacation communities. Finally, there can be substantial increases in population due to major festivals and sports events.

Identify the ERS and Its Capacity

Evacuations typically result in substantially more vehicles than normal attempting to use the ERS and, moreover, using those roads almost exclusively to travel in a single direction away from the hazard. Thus, continuing to use normal traffic control mechanisms such as stop signs and traffic signals – and even toll booths on tollways – can substantially delay vehicles attempting to reach safety. Consequently, it is necessary to designate the roads with the greatest capacity as the primary evacuation routes and to devise traffic management strategies that can be used to maximize their capacity.

The capacity of the ERS can be estimated in three steps. First, the analyst must identify the distinct set of links (individual road segments) that provide routes out of the risk area. Second, the analyst must assess the capacities of the individual links considering each link's number of lanes, shoulder type and width, intersection characteristics (including turn lanes and signal phasing), speed limits, and surrounding land use (Dotson and Jones 2005; TRB 2010). Third, the analyst must examine the configuration of the links in each evacuation route to determine whether they form a serial, parallel, converging, or diverging pattern. Serial links generally are limited by the smallest capacity in the set of links for that evacuation route – as when a link with an 800 vehicle per hour (vph) capacity overloads a link with a 600 vph capacity producing an overall capacity of 600 vph. It is also possible for the reverse to be true, as when a link with a 600 vph capacity underloads a link with an 800 vph capacity, also producing an overall capacity of 600 vph. However, there usually are additional vehicles attempting to access the downstream link, so a downstream link with greater capacity than the upstream link that feeds it usually becomes filled anyway.

In general, parallel links have additive capacities – as when two parallel links with capacities

of 800 vph have a combined capacity of 1600 vph. Diverging links (a single link splitting into multiple links generally follow the same rule as serial links because, here too, the capacity of the overall evacuation route is determined by the capacity of the link with the smaller capacity. Converging links (multiple links feeding into a single link) are problematic because traffic cannot merge seamlessly so the actual flow into the downstream route is likely to be lower than its nominal level.

It is important to recognize that link capacity can be degraded by both controllable and uncontrollable conditions. The controllable traffic impediments can usually be corrected (e.g., traffic accidents) or temporarily suspended (e.g., road repairs) to return traffic capacity to its normal level. The uncontrollable impediments (e.g., adverse weather) may require the use of compensatory actions such as additional evacuation routes or earlier evacuation initiation.

Estimate Evacuation Compliance and Shadow Evacuation

Evacuation managers should expect incomplete compliance with evacuation recommendations that is a function of authorities' labeling of the evacuation (recommended vs. mandatory) as well as people's perception of their distance from that threat (see Lindell and Prater 2007). However, they should also expect *shadow evacuation* – evacuation from areas that authorities do not consider to be at risk (Zeigler et al. 1981). Both incomplete compliance and shadow evacuation have been observed in both technological and natural hazards. In particular, evacuation shadow can reach surprisingly high levels. For example, the nuclear power plant accident at Three Mile Island produced about 150,000 evacuees in response to an evacuation advisory that applied to 10,000 people at most (Lindell and Perry 1983). Similarly, there was an estimated 47% evacuation rate from Harris County, Texas, for Hurricane Rita (Lindell and Prater 2008; Stein et al. 2010) even though less than 10% of the population was in the officially designated hurricane risk area.

Forecast Evacuation Demand

Following Urbanik et al. (1980), the time required for a household to evacuate after incident initiation can be defined as a function of four time components:

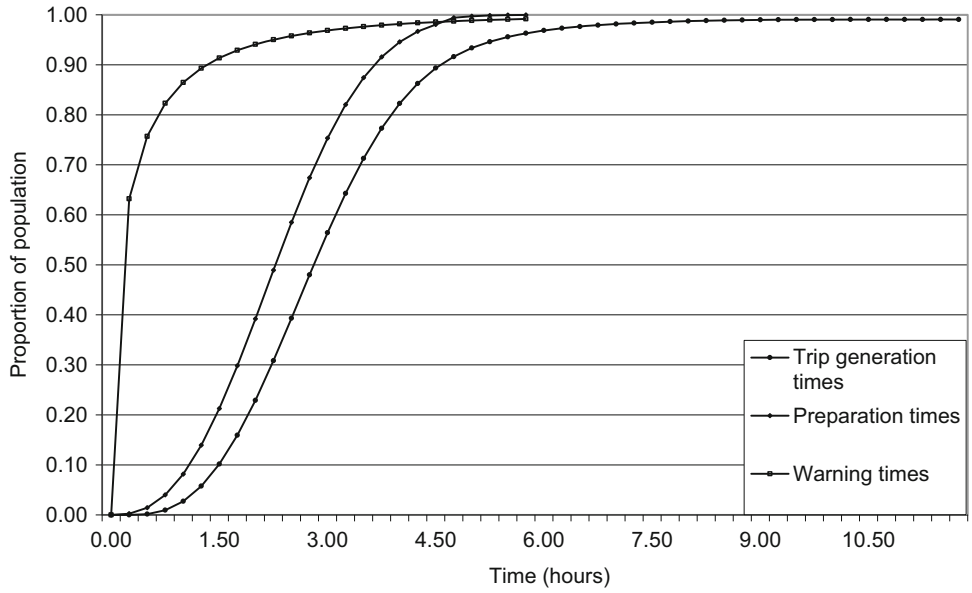
$$t_T = f\left(t_d, t_w, t_p, t_e\right) \quad (1)$$

where

- t_T is a household's total clearance time,
- t_d is the authorities' decision time,
- t_w is the household's warning receipt time,
- t_p is the household's evacuation preparation time, and
- t_e is the household's evacuation travel time.

Authorities' decision times (t_d) are critically important in rapid onset incidents for which there are no environmental cues, such as remote tsunamis and some toxic chemical releases. However, authorities' decisions can also be important in slow-onset incidents such as hurricanes because official protective action recommendations provide an indication of the time at which those at risk need to take protective action. The time to warning receipt (t_w) is highly variable because it depends on the nature of the local warning mechanisms. These warning mechanisms differ in many ways – with those having the lowest sender and receiver requirements (i.e., specialized equipment) having the slowest rate of dissemination (Lindell et al. 2018, Chap. 3). Household preparation time (t_p) is also highly variable because it depends on the amount of forewarning and people's threat perceptions. For example, people are likely to gather the family and leave immediately when they expect the imminent arrival of a toxic chemical release.

The first three components in Eq. 1 (t_d, t_w, and t_p) are combined to produce an estimate of the cumulative percentage of departing vehicles at each point in time (see Fig. 2). The resulting departure time distribution – the "loading function" – is multiplied by the number of evacuating vehicles to estimate evacuation demand – the rate at which vehicles enter the ERS. The rate of warning reception and evacuation preparation can each be represented as an exponential function,



Source: Lindell (2008)

Emergency Management: Evacuations, Fig. 2 Generic trip generation time distribution function. (Source: Lindell 2008)

$p_t = 1 - \exp(-at^b)$, where p_t is the proportion of the population prepared at time t, and a and b are parameters that determine the shape of the curve. For example, Lindell (2008) reported an analysis that used parameters $a = 2.00$, $b = 0.50$ for a representative warning time distribution and $a = 0.085$, $b = 2.55$ for a representative scenario preparation time distribution. These distributions would be appropriate for a rapid onset scenario such as a flash flood or hazardous materials release. However, they are inappropriate for hurricane evacuations in major metropolitan areas where evacuations take place over two or more days. In such cases, the departure time distributions *for each day* tend to have departure rates (per hour) that rise from 6 am to 6 pm, decline in the afternoon and evening, and drop to nearly zero overnight (Lindell et al. 2018, Chap. 5).

It is important to note that the shape of the warning distribution depends upon the nature of the warning system (Rogers and Sorensen 1988; Sorensen and Rogers 1989). The larger the percentage of the population that can be warned *simultaneously by broadcast systems* (e.g., siren and Emergency Alert System), the sooner the warning distribution will reach asymptote (the point at which everyone who can receive a warning does so). Conversely, the larger the percentage of the population that must be warned *sequentially by diffusion systems* (e.g., emergency responders going door-to-door), the later the warning distribution will reach asymptote. By contrast, the shape of the preparation time distribution depends upon warning recipients' perceptions of the urgency of the situation and their abilities to respond promptly. For example, people will begin their evacuations sooner for a chemical release in progress than for a hurricane that is 2 days away. In addition, able-bodied people whose families are united and who have emergency kits already packed will begin their evacuations sooner than those who lack these characteristics. In incidents with long forewarning periods, preparation time distributions cannot only consist of preparation to leave work, travel from work to home, and activities to prepare for the evacuation trip, but also intermediate trips to get money, and to purchase gas, food, and medicine.

The estimation of the ERS loading function is even more complex for situations in which there is no forewarning before hazard onset – *no-notice*

evacuations. In such cases, families are likely to be separated with, for example, two spouses working at different locations and multiple children at different schools. Families' attempts to reunify constitute an additional component of preparation time (before beginning their trip out of the risk area) that can produce inbound traffic into the risk area and cross-flows through the risk area. This delays households' own departures and disrupts outbound flows of traffic from those seeking to leave directly after receiving a warning (Murray-Tuite 2007; Murray-Tuite and Mahmassani 2003, 2004).

Model Traffic Behavior

Finally, household evacuation travel time (t_e) varies depending on the capacity of the ERS and the demand for space on that ERS. This time component is estimated using one of the available traffic optimization or simulation codes (see Lindell et al. 2018, Chap. 9). In a very simple case, the time required to evacuate a risk area could be estimated by dividing the number of evacuating vehicles by the roadway capacity (in vehicles per hour). Unfortunately, evacuations frequently produce demand that exceeds the available roadway capacity, thus producing queues of vehicles waiting for access to the roadway. The need to incorporate queuing time into the calculations means that modeling traffic behavior for any area other than a small neighborhood with an extensive road network requires complex computations. Only computer programs can adequately model the behavior of drivers as they leave their points of origin, drive to one of the principal evacuation routes, queue for access to the evacuation route, travel along that route to a proximal destination at the edge of the risk area, and travel from there to the household's ultimate destination where they will seek shelter. These models require analysts to input the data from the previous stages of the evacuation analysis – identifying risk areas/sectors, assessing the size of the risk area population, identifying the ERS and its capacity, and forecasting evacuation demand. These traffic modeling programs can generate data on total traffic volume; average vehicle travel time; risk area clearance time; hourly volume, total volume, and average speed at each exit from the risk area; and queue lengths at selected intersections (Jones et al. 2011). It is important to conduct sensitivity analyses using a range of plausible values for each of the major input parameters to see how model output data, especially evacuation time estimates, are affected (Lindell 2008).

Evacuation Management

The principal tasks involved in managing an evacuation are threat detection and emergency classification, protective action selection, population warning, evacuation transportation support, evacuation traffic management, reception and care (shelter accommodations), and re-entry management (Lindell et al. 2006). There are other response functions that must be performed in an emergency, but they are not directly related to evacuation management (see *Emergency management: Crisis management and response*).

Threat Detection and Emergency Classification

Sometimes, as was the case in the 1978 Sumner Washington flood, the risk area population needs no assistance in detecting and classifying environmental conditions as immediately dangerous (Perry et al. 1981). In other cases, such as hurricanes and nuclear power plant accidents, specialized agencies are needed to detect a hazard, forecast the areas it is likely to affect, and assess the severity of the threat to people and property – thus indicating the need for sheltering in-place or evacuation. For example, the National Weather Service uses two emergency classes, *Watch* and *Warning*, to define the certainty, severity, immediacy, and intensity of the threat at designated locations. Once the agency (or facility in the case of nuclear power plants and chemical facilities) detects and classifies the threat, it needs to notify local emergency managers so they can decide whether to initiate protective actions such as evacuation. However, Sorensen and Rogers (1988) found that few communities had adequate mechanisms for receiving notifications about incidents from chemical facilities within their

jurisdiction and other studies have found delays in receiving and acting on such threat notifications (Lindell et al. 2017; Sorensen and Mileti 2016).

Protective Action Selection

It is important to recognize that evacuation is unnecessary – and might be dangerous – for those who can achieve protection by sheltering in-place (Cova et al. 2009; Jetter and Whitfield 2005; Lindell and Perry 1992; Sorensen et al. 2004). Sheltering in-place within buildings is effective when these structures are elevated above the flood crest, are strong enough to withstand hurricane wind, can withstand wildfires, are dense enough to provide shielding from external radiation, or have sufficiently low air exchange rates that they delay the infiltration of contaminated air (*Emergency management: Sheltering in-place*). In addition to deciding which protective actions to recommend, local authorities need to decide when to initiate those protective actions. That is, "who should be warned to do what and when?" (Cova et al. 2017; Lindell et al. 2018, Chap. 3).

Population Warning

Warnings are crucial elements in initiating evacuation, but emergency managers need to understand the best ways to construct and transmit them (see Lindell 2018; Lindell and Perry 2004). First, a warning message should indicate the warning source, describe the threat in terms of its expected impact intensity, timing, and location, provide a recommended protective action, and indicate sources to contact for further information about the situation and to obtain assistance in taking protective action. Warnings should be transmitted repeatedly on each channel and disseminated via multiple channels so people receive, attend to, and understand the warning message.

There are many different channels for disseminating warnings to those at risk (*Emergency management: Emergency alert systems*). These are face-to-face warnings, mobile loudspeakers, sirens, commercial radio and television, NOAA Weather Radio, telephones, email, Internet websites, social media such as Twitter, and newspapers. Each of these mechanisms can be evaluated with respect to eight characteristics. These are precision of dissemination (the ability to target only those at risk), penetration of normal activities (especially the ability to overcome ambient noise), specificity of the message (the ability to convey all of the elements of an ideal warning message), susceptibility to message distortion (a problem that arises when a warning message must be passed through one or more intermediate communicators), rate of dissemination over time (the time between receipt by the first and last warning receivers), receiver requirements (especially expensive equipment or specialized knowledge and skill), sender requirements (also expensive equipment or specialized knowledge and skill), and feedback (sender verification that the receiver has received the warning). Communities need to choose which warning channels they will use based upon the characteristics of the hazard (especially the amount of forewarning, the size of the impact area, and the likely impact intensity) and the community's financial resources (Lindell et al. 2018, Chap. 3).

Evacuation Transportation Support

As noted earlier, some segments of the risk area population lack vehicles or have other obstacles to evacuation. For the transit dependent, local authorities need to make arrangements with school districts or mass transit providers such as transit districts. Emergency managers need to verify that transit providers have not made arrangements with other jurisdictions that would need buses at the same time. Such duplicate demands could arise if the providers signed agreements with officials in two different counties on the assumption that these agreements would be activated only for very local evacuations that would not require simultaneous evacuations in multiple jurisdictions (Daines 1991). Similar caution must be taken to review concurrent service agreements for multiple hospitals and nursing homes, which have the added requirement of ensuring that there are available beds in receiving facilities before transporting patients (Auf der Heide and Scanlon 2007). Moreover, care must be taken to ensure that the number of buses, ambulances, and other

vehicles is sufficient to accommodate the maximum capacity of these facilities. Criteria for transporting pets need to be made and publicized via the news media before and during an incident (Heath et al. 2001).

Evacuation Traffic Management

There are two fundamental strategies for evacuation traffic management: ERS capacity management and evacuation demand management. ERS capacity management seeks to minimize or avoid queues that form when too many vehicles compete for space on the roads or to increase capacity through procedures such as contraflow. Evacuation demand management seeks to regulate the number of vehicles attempting to use the ERS at any given point in time so that maximum capacity is maintained for a given lane use configuration.

ERS capacity management. The most common evacuation impediments are ERS capacity and ERS condition (Vásconez and Kehrli 2010). Accordingly, maintaining – and if possible increasing – ERS capacity is a major issue in managing an evacuation. The primary methods for maintaining ERS capacity are intersection control and prompt clearance of traffic impediments such as vehicles blocking traffic lanes due to overheating, running out of fuel, and collisions (Ballard and Borchardt 2006; Jones et al. 2011; Wolshon et al. 2005). Some traffic impediments can be avoided by, for example, stationing fuel tankers along evacuation routes to avoid allowing evacuating vehicles to run out of fuel. Some collisions can be cleared by other evacuating vehicles that push the incapacitated vehicle off the roadway, but others require authorities to station tow trucks along the evacuation routes.

The primary methods for increasing ERS capacity are utilization of highway shoulders as *evaculanes,* crossing elimination, special signal timing, and implementation of contraflow – reversing the direction of inbound lanes (Jones et al. 2011; Wolshon et al. 2005). Utilizing shoulders as traffic lanes has some distinct limitations such as precluding their use for emergency vehicle access to accident sites (Ballard and Borchardt 2006). Moreover, they also only increase capacity by a small amount (estimated to be 8%, Wolshon et al. 2005). However, the cumulative effect of even this small capacity increase could be significant if implemented over multiple evacuation routes.

Special signal timing limits the amount of time allocated to crossing and turning maneuvers at intersections on designated evacuation routes, whereas crossing elimination prevents them altogether. In both cases, the objective is to maximize the flow of traffic on the outbound route away from the hazard zone. Contraflow reverses the direction of one or more travel lanes from inbound (toward the hazard zone) to outbound. Planning for contraflow requires careful planning because a full contraflow configuration provides more outbound capacity, but partial contraflow configurations (reversing only one of two inbound lanes) provide an opportunity to maintain one or more lanes in their normal inbound configuration for returning buses and emergency vehicles. This obviously increases outbound capacity by a smaller amount (about 30%) than a complete contraflow configuration (about 70%) and also increases the potential for head-on collisions. Regardless of which contraflow configuration is selected, evacuation managers need to correctly anticipate the length of time required to implement it, which range from 4 to 12 h, depending on the length and complexity of the contraflow segment (Wolshon et al. 2005).

Evacuation demand management. The primary methods of demand management are to control the total number of people seeking to use the evacuation routes, control the allocation of vehicles to evacuation routes, and control the loading of the ERS. One important method of demand management is to avoid shadow evacuation from outside the officially designated evacuation zones. As noted earlier, shadow evacuation has added substantially to the number of vehicles in some past evacuations. In addition, evacuation managers can reduce the amount of background traffic, which consists of vehicles attempting to use the evacuation routes for routine travel, by controlling access to the evacuation zone. The need for evacuation from inside the risk area can also be reduced if local structures are adequate for sheltering in-place. Moreover, the occupants must

believe that these structures provide effective protection before they will comply with a shelter in-place recommendation.

Another demand management strategy is to reroute evacuation traffic from overutilized routes to underutilized ones. This could be an effective strategy because people tend to use the most familiar routes to their evacuation destinations (Lindell and Prater 2007). Unfortunately, such habits tend to overload freeways and underload minor highways (Dow and Cutter 2002). The challenge in redirecting traffic is for authorities to identify the alternative evacuation routes from specific originating points to specific destinations and to communicate in real time what are average speeds on these routes. This strategy is increasingly feasible with the development of intelligent transportation systems that are capable of monitoring and directing traffic.

In principle, ERS loading can be controlled by phased (also called "staged") evacuations in which people in areas of lower risk are asked to delay their evacuations until after people in areas of higher risk have evacuated (Jones et al. 2007, 2011). Phased evacuations have been used many times in hurricanes and wildfires (Jones et al. 2008). However, conclusions about their utility appear to be based only on anecdotal evidence of success (i.e., an absence of spectacular failures) rather than collection and analysis of empirical data. To implement phased evacuation effectively, evacuation managers need high levels of evacuee compliance with the phased evacuation recommendation and an ability to forecast accurately how soon people would begin to evacuate after a delayed evacuation advisory is issued. Unfortunately, there is no research on the amount of time people are willing to delay their evacuations while others are leaving. To the contrary, the available behavioral research indicates that people believe that sheltering in-place provides less effective protection than evacuation for toxic chemical releases (Lindell and Perry 1992). Experts are also highly uncertain about people's willingness to comply with a shelter in-place recommendation in a radiological release (Dombroski et al. 2006), and observation of others evacuating is a social cue that prompts people to leave (Huang et al. 2016). Notwithstanding these uncertainties, there is a natural tendency for those farther inland to begin their hurricane evacuations later than those near the coast (Lindell et al. 2011; Wu et al. 2012). This has the potential to create traffic jams if inland residents try to enter the ERS as the same time coastal residents are arriving there. Fortunately, this convergence of coastal and inland evacuees has the tendency to produce evacuation queues in inland areas where the risk of being overtaken by the hurricane surge is relatively low.

Reception and Care

When evacuations last overnight or longer, people need places to stay until it is safe to return home. The types of accommodations people choose is well studied, with researchers finding consistently that only a small percentage of evacuees use public shelters. The Mileti et al. (1992) review concluded that only 15% of evacuees go to public shelters, which are primarily occupied by ethnic minorities, the poor, and those who depart too late to find hotel/motel vacancies. The Lindell et al. (2018, Chap. 6) review of hurricane evacuation studies found that 62% of evacuees stayed in peers' homes (range 54–70%), whereas 27% stayed in hotels/motels (range 16–32%), and only 3% stayed in public shelters (range 2–6%). That estimate of hurricane shelter usage is significantly lower than Mileti and his colleagues' (1992) estimate for evacuations in general – probably because hurricanes provide so much forewarning that people have an adequate amount of time to make arrangements for accommodations with peers or commercial facilities.

Re-entry Management

Managing evacuees' re-entry after an evacuation can be a major challenge for emergency managers. Achieving high levels of compliance with official re-entry plans has been difficult following past hurricanes (Siebeneck and Cova 2008), so there is a need to better understand the factors that influence the timing of evacuees' re-entry attempts. Siebeneck et al. (2013) found that Hurricane Ike evacuees who complied with official

re-entry plans expected greater problems being stuck in traffic and expected less physical risk from damaged structures. There were no statistically significant relationships of re-entry plan compliance with expectations of looting, income loss, utility loss, and socio-demographic characteristics.

Because many evacuees rely on news media as a source of information about their communities while evacuated (Siebeneck and Cova 2008), it is important to gain a better understanding of what information – or misinformation – the news media are communicating and how this, in turn, shapes the expectations and behavior of the evacuated population. Lin et al. (2014) found significant changes in the utilization of different sources of emergency information over the course of the Hurricane Ike evacuation, but local news media remained the most common sources throughout the event. There also were significant differences in the relative importance of different sources of reentry information, with people relying most on information from peers. Nonetheless, none of the information sources produced greater compliance with official reentry plans.

Conclusions

Evacuations can be managed effectively, but the larger the scale of the evacuation and the shorter the amount of forewarning, the greater is the need to plan, analyze, and manage effectively. Effective planning requires coordination among diverse agencies at different levels of government (municipal, county, state, and federal), as well as with nongovernmental organizations such as the Red Cross. Effective analysis requires identifying risk areas/sectors, assessing the size of the risk area population, identifying the ERS and its capacity, forecasting evacuation demand, and modeling traffic behavior. Effective evacuation management requires incident detection and classification, protective action selection, warning, evacuation transportation support, evacuation traffic management, shelter accommodations, and re-entry management. Evacuation managers have the best chance of protecting the risk area population from environmental hazards if they address all of these issues successfully. In addition, they should work with local emergency managers to increase households' and businesses' levels of emergency preparedness (Lindell 2013; Lindell and Perry 2007; Perry and Lindell 2007). Finally, historical evidence indicates that sound traffic management (for the evacuation of the general public by automobile) and a normal level of medical precaution (for hospital evacuations) are sufficient to assure the safety of the evacuating population.

Emergency Management: Incident Command System

Dorothy Moses Schulz

Keywords
Risk · Vulnerability · Disaster management

Definition

Emergency management describes the activities of professionals in a number of fields intended to manage resources to reduce vulnerability to hazards and to cope with disasters that may have been created as a result of accidents, by individuals (such as terrorists or active shooters) or by nature (such as floods, earthquakes, tsunamis, or wildfires). The Incident Command System (ICS) facilitates managing these activities by integrating multiple agencies' facilities, equipment, personnel, procedures, and communications into a common organizational structure that is scalable to the size and type of emergency, is applicable across disciplines, and can be used to organize immediate and long-term field operations for natural or manmade incidents.

Introduction

Emergency management is not only about *responding* once an incident has occurred, it also includes the agencies and activities responsible for *protecting* against an event's occurrence, *mitigating* the consequences of and *recovering* from the event. Each step requires coordination among federal, state, tribal, local, and cross jurisdictional government agencies; educational and health-related institutions; utilities and communications providers; nonprofit, social service, and community-based organizations; and private companies. Emergency management focuses on measuring

and managing risk. Risk managers undertake assessments to consider the probability (likelihood) that an event will occur and its consequences (damage to people, property, or the environment and how much money, time, and other resources it will take for recovery). They may consider, for instance, the risk of a toxic chemical spill following a train derailment or truck accident; of a flood, tsunami, wildfire, or earthquake; or of an active shooter at a school or shopping mall. Once they have assessed the risk, they consider how to manage it, which includes developing an Incident Action Plan (IAP) should the event occur.

Individuals will assess risk and determine how to manage it daily, but do not think of it as risk management. If you avoid a part of town you believe is unsafe or if you decide not to take an umbrella when rain is predicted, you have assessed risk. In the first case, you are weighing the risk of becoming a crime victim, in the second, the likelihood of getting rained on. In both, you considered risk based on probability (how likely is it to happen) and consequence (how bad will it be). This entry describes the development of disaster relief and emergency management, explains the ICS protocols, and discusses the applicability of those protocols to different types of events.

Early Disaster Relief

The U.S. government's involvement in disaster relief is acknowledged to have begun on February 19, 1803, when Congress passed the Relief of Sufferers by Fire in the Town of Portsmouth [New Hampshire] Act to make federal resources available in response to a December 26, 1802 fire that devastated the town. The Act authorized "the Secretary of the Treasury to suspend, for a limited time, the collection of bonds due to the United States by merchants. . .who. . .suffered by the. . .conflagration. . ." (City of Portsmouth 2016, p. 7). This was required because Congress lacked authority to pass laws that applied to specific states (and by extension, areas within states). It was unconstitutional for Congress to allocate money from the Treasury or to suspend funds due the Treasury as a form of relief.

Between 1803 and 1950, Congress passed more than 100 ad hoc laws to provide relief or compensation to individuals or localities after disasters (Drabek 1991, p. 6). The 1950 Disaster Relief Act (DRA) (Public Law [PL] 81–875; amended in 1974 as PL 93–288) eliminated the need for event-specific disaster aid packages by creating a permanent, national disaster relief program and encouraging states to develop disaster plans (Yoshpe 1981, p. 523; Birkland 1997, p. 49) and it transferred the authority to declare a disaster from Congress to the President. Natural disasters in the 1960s and 1970s led, in 1974, to amending the DRA to allow the federal government to provide individual and family assistance after a disaster. A National Governors' Association (NGA 1978) report highlighted concerns that the federal government lacked a national emergency policy and that the large number of agencies assigned disaster responsibilities made it difficult for states to manage these events. The NGA advocated for greater state/local discretion in using federal funds and for a greater focus on prevention and recovery, rather than primarily on activities during a disaster.

National Incident Management System (NIMS) and the Incident Command System (ICS)

Upon creation of the Federal Emergency Management Agency (FEMA) in 1978 by President Jimmy Carter, its first permanent director, John Macy, tried to create an integrated emergency management system (IEMS) that would provide a multi-hazard approach, depended on professional management at the state and local levels (Greenstone 1989, p. 22), and could be used to manage nature-made disasters as well those created by intentional acts. This approach remains the basis of today's National Incident Management System (NIMS) and Incident Command System (ICS).

Also foreshadowing NIMS and ICS, Congress in 1988 passed the Robert T. Stafford Disaster

Relief and Emergency Assistance Act (PL 93-288 as amended; further amended by the Disaster Mitigation Act of 2000 and the Pets Evacuation and Transportation Standards Act in 2006). The Act, named for its chief sponsor, Sen. Stafford (R-VT), authorized the federal government to handle emergency assistance and response activities; increased cost sharing from a 50/50 ratio to 75 % federal/25 % state/local; expanded cost sharing to include public assistance programs; redefined the meaning of an eligible private, nonprofit facility, and authorized family grant and disaster housing programs. It places a limit on the President's ability to declare a disaster by specifying the federal government may become involved only after a state's or territory's governor has requested assistance. This may be overridden only when it is apparent the state is unwilling or unable to fulfill its basic governmental functions.

The Stafford Act formalized FEMA's role coordinating government-wide relief efforts and required local or tribal governments to develop disaster mitigation plans and to establish implementation strategies. States must also develop plans and must explain how they will support local/tribal governments in fulfilling their plans. Preparing for hazards must include creating preparedness plans, recruiting and training personnel, conducting research, stockpiling materials and supplies, creating warning systems, and constructing shelters.

Within less than a month after the September 11, 2001 terrorist attacks in New York City, Washington, DC, and Shanksville, Pennsylvania, President George W. Bush issued Executive Order 13288, which led to creation of the Department of Homeland Security (DHS). FEMA was one of the 22 federal offices and programs moved into DHS, where it is housed in the Emergency Preparedness and Response Directorate. Since March 2004, under Homeland Security Presidential Directive (HSPD) 5, *Management of Domestic Incidents*, states and territories must maintain an office of emergency management whose funding comes principally from FEMA and from the jurisdictions' budgets. These offices are often located in state offices of homeland security, where they coordinate emergency planning, disaster drills involving multiple agencies, and public outreach. To be eligible for disaster preparedness funds, federal departments and agencies; state, local, and tribal governments; the private sector and nongovernmental organizations (NGOs) must use NIMS to integrate domestic prevention, preparedness, response, and recovery plans into a single all-discipline, all-hazards plan and they must employ ICS to manage on-scene response activities.

Similar to FEMA's concept of IEMS, NIMS is designed to help agencies define roles and responsibilities in an event and develop procedures to manage emergency operations. It is a template for agencies to work together during emergencies. It is intended to be flexible and scalable to allow agencies to plan for and respond to incidents regardless of cause, size, complexity, or location. ICS is an essential element of NIMS. Like NIMS, ICS is intended to provide a standardized approach to event management by outlining procedures that can be used regardless of an incident's type, location, duration, and the number and types of responding agencies. Many of the ICS protocols were developed in the 1970s by agencies fighting wildfires in California and other Western states. Because many of the agencies had never worked together, time and equipment were squandered, leading to the realization that they needed a coordinated approach such as ICS to bring personnel, equipment, procedures, and communications under a common structure to manage resources during and after an incident.

ICS is structured for activities in five areas: command, operations, planning, logistics, and finance/administration.

Command. ICS is based on the concept of unified command, which means that all responders work as a team under the same command structure and are not hindered by organizational boundaries that would require them to get direction only from their own agency (National Incident Management System 2014, pp. 11–12).

To assure that unified command is followed, key roles are defined. The Incident Commander (IC) is in charge and is responsible for all activities. In an incident, the first person on the scene is the IC until replaced by someone with higher rank

and/or greater expertise. Once the IC is identified, a unified command is established at the Incident Command Post (ICP) to which all responders report to receive their assignments. The Incident Commander should make the initial assessment of the situation unless relieving an earlier Commander. In that case, the oncoming IC must obtain a briefing from the IC being relieved. Once the IC has determined the incident's objectives and strategy, she/he must establish priorities and a Command Post (ICP) if it has not been previously established. After authorizing implementation of the incident action plan, the IC must assure that safety measures are in place; coordinate activity for all Command and General Staff and with key people and officials, and authorize release of information to the media. A key part of command authority is requesting additional resources or releasing of resources that are no longer required at the incident site, including ordering demobilization of the incident when appropriate.

A number of individuals make up the Command Staff, each of whom reports to the IC. These include the Liaison Officer, the Safety Officer, and the Public Information Officer (PIO). The Liaison Officer assures that personnel, regardless of their agency, receive similar instructions and are aware of their roles. The Liaison Officer assists the IC in maintaining contact with all the agencies involved in the incident, whether as responders or in some other role. This officer is responsible for identifying and minimizing miscommunications that may arise among agencies. The Liaison Officer may also advise officials not on the scene, including local government officials and senior personnel from the responding agencies, to assure that everyone receives the same information.

The Safety Officer is the senior safety official at the scene and is responsible for ensuring that safety, health, and environmental hazards are assessed. Assuring the safety of responders may include assessing and/or anticipating hazardous situations such as the presence of dangerous chemicals or whether a facility is structurally safe to enter. This officer is also generally responsible for assuring medical capabilities at an incident and coordinating with medical providers at the scene. A key role of the Safety Officer is to assure that all responders are accounted for before a scene is cleared. For example, at a train accident, the Safety Officer must assure that no one remains on the tracks before trains are permitted to resume service. In a fire or explosion, the Safety Officer assures no one is left behind in a smoldering or collapsed building.

The PIO interacts with and briefs the media and the public. Responders should not interact with the media; they should refer questions to the PIO. To assure a consistent message, ICS calls for establishing a Joint Information Center (JIC) with one PIO speaking for all the agencies. Because of the ubiquity of social media, a PIO may be assisted by someone who provides updated online information. In some circumstances, more than one PIO may be designated to speak on behalf of the IC. Generally, this occurs in a multisite situation where it is difficult for one person to be aware of what is happening at each site. A second PIO may also be assigned if the situation results in many victims or responders being taken to a medical facility, where a PIO may be located specifically to provide medical updates to the media. In any multiple-PIO situation, it is very important that the PIOs coordinate closely before releasing any information since inconsistent messages are likely to contribute to misunderstanding by the media and the public and could, in certain situations, cause confusion and even panic.

Operations. Operations personnel manage tactical operations at the incident based on the existing IAP – they are the actual responders. Operations section personnel manage the incident site to reduce the immediate hazard, including saving lives and property, establishing situation and site control, and restoring the situation to normal conditions. Incidents can include natural disasters such as wildlife or urban fires and floods; earthquakes; and hurricanes, tornadoes, or tropical storms. Other types of incidents are acts of terrorism or war-related disasters; hazardous materials sills, nuclear accidents; aircraft or train accidents; or public health or medical emergencies. While some incidents will require highly specialized operations responders, virtually all will include such operations personnel as fire,

law enforcement, and emergency services. Others might require assistance from public health or public works personnel, for instance, if many individuals must be treated at the scene or transported to area hospitals or if facilities must be blocked off or declared unsafe for occupancy. The Operations section is likely to also include individuals from private companies or non-governmental organization who have skills and qualifications beyond those held by public-agency personnel. This is why it is important that the planning process include not only public officials but also private sector managers who have access to personnel and equipment that many governments may lack either due to their small size or small budgets.

Planning. Planning staff collects, evaluates, and processes information to develop the IAP; this is likely to include an inventory of physical resources, specialized data, alternative strategies, and availability of specialists whose skills may be required to resolve an incident or for follow-up during recovery. Planning is a process that starts well before an incident takes places and continues long after the incident has been resolved. Almost all discussions of emergency management contain information on the planning function; while the descriptions might differ somewhat, the functions are always similar.

Different types of agencies may label the planning steps differently or break them into larger or smaller components, but generally planning covers the following steps.

Hazard analyses and capability assessments. A hazard analysis is a formal study of what might happen and what might go wrong in certain types of situations. It can be as basic as going through a facility to determine where hazards exist such as unsafe conditions or places trespassers could enter, or it could try to determine how likely a facility is to be an attractive terrorist target (possibly based on what type of product is produced there, or how important it is to the surrounding area as an economic or social resource, or what the publicity value would be to the terrorist organization in attacking that facility). Once a hazard has been identified, the likelihood of an event taking place must be considered but so must be a capability assessment, which requires the planners to ask themselves how capable their jurisdiction would be in preventing, responding, or recovering from an incident that might happen. These questions must be asked by the planners so they can consider what personnel, equipment, or other resources would be needed in the event the incident occurred.

Based on their assessment, the planners must now develop the IAP – what will the jurisdiction do if the incidents described in the plan or anything similar actually happens?

To assure that the IAP is viable, the knowledge, skills, and abilities that it relies on must be maintained. Generally, this is done through continuing education and training exercises. Agencies plan emergency response drills based on the type of incident they believe they might be faced with. For instance, transit agencies might have agency personnel train with federal, state, and local first responders to an exercise simulating a derailment, an active shooter situation at a train station or on a train, or an accident with multiple fatalities or a hazardous materials spill from a leaking freight car. Hospitals, schools, shopping malls, sports venues, and places of worship are more likely to have drills focusing on active shooters or hostage takers, although some might simulate terrorist activity if they believe they are likely targets. In all cases, the training activity should be based on a situation that could possibly occur at that type of facility since the goal is to measure the readiness of responders should such an event occur.

Based on the training event, planners and responders will evaluate the response. If there is a knowledge or capability shortfall (people do not know what to do or they lack the resources to do it), the planners must either re-evaluate the usefulness of their plan, making changes or developing strategies to bring the responders and materials up to what the plan calls for.

Demobilization. In the event of an actual incident, demobilization activities often fall to planners. In addition to assuring that resources are returned to their original source, planners are often responsible for collecting incident-related documents that must be reviewed with the goal

of assessing response. Like training events, documents, and post-incident reports will be used to reassess and revise an existing plan for future use.

Throughout these steps, the planners must consider where their resources will come from. Are there federal funds or other assistance available? What specialized skills exist within nongovernmental or private agencies? How would people be evacuated from their homes and where would they be temporarily housed? How close are area medical facilities and what resources do they possess or lack that would be important in a disaster emergency? Once this type of information is collected, reviewed, and evaluated, it must be shared with those who will be responsible for carrying out any activities. Planning is an ongoing process; the IAP will generally be reviewed and modified at least annually to incorporate changing conditions and changing resources.

Logistics. Logistics entails the coordination of complex operations that involve many people, facilities, or supplies, most often from more than one source. In a business environment, logistics is defined as managing the flow of how things get from their point of origin to the point of consumption, or where something is made or grown to where the customers are. In emergency management, logistics describes making sure that all resources are in place or will be available when needed. This means that logistics personnel are responsible for assuring that support needs are met; this will include facilities; transportation; communications; supplies; equipment maintenance and fuel; food and medical services for responders; and off-incident resources.

Logistics personnel play a key role in IAP development; they are often responsible for creating protocols to assure that support networks are in place. For instance, if certain types of vehicles or machinery are required for certain situations, what local agencies have them and how quickly can they be brought to the incident site? In mass injury events, it is crucial to know the distance to each area hospital and the capabilities of each to handle various types of medical emergencies. Logistics personnel also have an important role after an incident has been resolved since their recording of what agencies supplied personnel and equipment can be crucial to assure that compensation and claims are properly apportioned among the agencies and charged to FEMA, insurance agencies, or others responsible for reimbursement after accounts are reconciled.

Finance/Administration. Finance/Administration personnel provide financial and/or administrative services support to incident management activities. Because funds may come from many different sources and may be charged to different accounts within those sources, all incoming funds such as government grants or contributions from private sector participants must be recorded and tracked, as must be funds expended during an incident. In some instances, where it can be anticipated that certain equipment will be needed for certain types of incidents, a jurisdiction may decide to purchase the item; in such cases,[note bad margin break] Finance/Administration personnel are most likely to be responsible for disbursing the funds, controlling documentation of the purchase, and possibly determining where and how the equipment may be used under non-emergency conditions. They also manage the costs of an incident, including ensuring that responder costs (salary, overtime, travel vouchers, lodging, and meals) and any costs of purchases associated with response are accurate and complete.

Difficulties Assessing ICS in Different Types of Emergencies

Assessments of the benefits of ICS are mixed. Although ICS is used by agencies for many types of events, analyses focus on unusual or unexpected incidents (generally disasters) rather than on agencies' implementation of ICS for planned events. Agencies implement ICS protocols for concerts, parades, state or county fairs, or major sporting events (the World Series, the Super Bowl, or a marathon) but these rarely receive post-event attention unless major glitches occur. In addition, because discussions of ICS as an emergency management tool tend to focus on specific disasters rather than on ICS protocols generally, the analyses lack guidance on how to deal with the next disaster. The lack of general ICS assessment

is reinforced by post-incident (or after-action) reports, which normally gauge participants' response to *their* incident and how to improve *their* response, rather than on global concerns. Also, because responses to emergencies and disasters have political implications, politicians' post-event comments are likely to differ from the after-action reports of the participants and to contain vague promises of doing better next time rather than detailed policy discussions.

An example of this type of internal review occurred in Baltimore, Maryland, following demonstrations in April 2015 after the death of Freddie Gray while in police custody. The report noted that ICS was neither well-understood nor were NIMS principles adhered to by responding agencies. The after-action report found that authority of the Incident Commander (IC) was contested by senior members of the Baltimore Police Department (BPD); that the role of the emergency operations center (EOC – the name often applied to ICPs) was unclear and resulted in confusion to where responders should report to receive instructions despite policies outlining the EOC's role, that some agencies were unfamiliar with NIMS and ICS, and that many liaison personnel lacked the rank or authority to represent their agency. The report recommended assuring that the IC has full authority to manage an incident; that the location of the EOC be communicated to all responders and that expectations that all report there are reinforced, and that all agencies, particularly BPD, enhance ICS capabilities through training and more frequent utilization of ICS principles in routine incident management (Links et al. 2015, pp. 21–22). Although a decade apart, these findings echo comments in FEMA's Facilitator Guide to NIMS that "the most common cause of response failure is poor management" and that "confusion about who's in charge of what and when, together with unclear lines of authority, have been the greatest contributors to poor response" (FEMA 2004, pp. 2–2).

Generally, ICS has been deemed most successful among firefighting organizations (who were involved in developing it) and less successful with law enforcement, public health, and public works organizations (Baltic 2004). Others have pointed to successful implementation of ICS when events are confined geographically, when responding agencies share outcome goals, and when the agencies involved are familiar with ICS and familiar with each other. Two examples illustrate these observations.

The April 19, 1995 bombing in Oklahoma City, Oklahoma, that resulted in the collapse of the Alfred P. Murrah Federal Building left 168 people dead and hundreds injured after being set by anti-government militant Timothy McVeigh. ICS contributed to successful incident management because it was supervised from the start by the Oklahoma City Fire Department (OCFD), whose commanders were trained in ICS and who retained command throughout. The event involved primarily one heavily damaged building with a secure perimeter that called for skills urban search and rescue team and firefighters are trained to have. Although many of the responding agencies had not worked or trained together, they were familiar with and had participated in ICS training, and were able to use their knowledge to coordinate their response to the incident (Buck et al. 2006, pp. 7–8).

The Deepwater Horizon oil spill in the Gulf of Mexico presented a different set of challenges that undermined the benefits of ICS. This incident began on April 20, 2010 when a British Petroleum (BP)-operated well discharged an estimated 4.9 million barrels of oil into the Gulf before the well was declared sealed on September 19, 2010. Legal issues surrounding the case went on for years; in 2012, BP and the US Department of Justice settled criminal charges including BP pleading guilty to 11 counts of manslaughter, two misdemeanors, and lying to Congress, and agreeing to government monitoring of its safety practices. Additional payments were agreed to by BP in 2013, 2014, and 2015.

Analysts noted that competing goals and messaging by BP and the government agencies involved in the response prevented establishing either a unified command or unified messaging. In addition, many responders had little knowledge of and belief in NIMS and ICS protocols. Critics debated whether differing private and government goals may present inherent problems in

establishing the unity that ICS requires and whether the incident was spread over too large a geographical area for ICS to work effectively (McKay 2010). These examples point to problems relying on universal protocols that, although scalable and flexible, may not be elastic enough to meet all situations, particularly where there are conflicting goals or where responders have received little emergency response training.

Conclusion

Emergency management has developed from an ad hoc system of the federal government providing relief after a specific disaster to federal requirements that governments and NGOs have detailed IAPs that mandate use of NIMS and ICS protocols by responding agencies. While NIMS and ICS have added structure to emergency planning, response, mitigation, and recovery, reliance on the protocols has differed among agencies and types of incidents, and agencies employing the protocols have met with different levels of success. To counter this, in addition to encouraging greater training and relying solely on post-event analysis, government officials and emergency managers may need to recognize that the size and complexity of some events, as well as possibly conflicting goals among responders, may undermine ICS during some emergencies and that some modification of the ICS principles may be required to assure the high-level of emergency response that the protocols are designed to ensure.

Emergency Management: Infant and Young Children Feeding in Emergencies

Sarah E. DeYoung
University of Georgia, Athens, GA, USA

Keywords
Infant feeding · Evacuation · Maternal and child health

Definition

The field of infant and young child feeding in emergencies (IYCF-E) is a set of practices, policies, and guidelines related to ensuring safe feeding of infants and young children during disasters and major hazard events.

Introduction

During large-scale evacuation and sheltering scenarios, families with infants need support for safe infant feeding. In the post-disaster setting, breastfed, bottle-fed, and mixed-fed infants require special care and support. Breastfed infants have a higher likelihood of survival in emergency scenarios (Jakobsen et al. 2003; WHO and UNICEF 2003; WHO 2015). Another benefit of breastfeeding is that infants are less likely to suffer from respiratory illness and other infections (WHO and UNICEF 2003). Breastfeeding improves health outcomes for women and infants (Rollins et al. 2016), and breastfeeding promotion provides resilience and protection for vulnerable groups in disasters (Gribble 2018). Distribution of commercial complementary foods (CCF) in emergency sheltering spaces can also be problematic because it may disrupt breastfeeding (early introduction of solids) and because the CCF may not contain the proper nutritional contents for toddlers and older children. Specifically, fortified complementary foods are nutritionally superior (Theurich and Grote 2017). Another issue for young children in emergencies is meal frequency and malnutrition during displacement and the post-disaster context (Sun et al. 2013).

Overview

Natural hazards, crisis and conflict, and other emergency settings can have adverse impacts on families with infants and young children. Breastfeeding is the safest form of infant feeding in disasters and emergencies and is the most cost-efficient intervention in vulnerable populations (Rollins et al. 2016). The context of the disaster event and access to resources are important in designing effective implementations for IYCF-E. For example, lack of access to clean water and supplies to sterilize feeding supplies makes safe bottle-feeding difficult in low-resource contexts, such as in a refugee camp (Gribble 2014; Prudhon et al. 2018). In high-income countries, lack of space in emergency sheltering facilities for breastfeeding, temporary interruptions in utilities, and other factors can pose challenges for families with infants (Callaghan et al. 2007; Gribble and Berry 2011). There are several factors that contribute to problems associated with poor IYCFE adherence. During disasters, media messages often contain myths of inaccurate information about infant feeding (Gribble 2013). These myths influence donor behavior and health workers' interactions with caretakers. These myths include (1) myths about milk/lactation "drying up" because of stress from the disaster event (e.g., DeYoung et al. 2018), (2) myths about maternal nutrition and breastfeeding, and (3) the myth of formula as essential. Another major problem that unfolds during disasters is the untargeted mass distribution of infant formula. This results in some families receiving breastmilk substitutes (BMS), although they were exclusively breastfeeding, and some families not getting the proper BMS. Other problems related to logistics may affect infant feeding. For example, in a mass-sheltering scenario, relief groups may distribute

formula without preparation instructions (and not in the user language).

Short-Term Sheltering

All efforts should be made by emergency personnel to keep families together, especially infants and mothers. Families should be assessed for feeding status at entry into emergency sheltering (bottle-feeding, breastfeeding, mixed feeding, combined with multiple children). Families that were exclusively breastfeeding before the disaster should be encouraged to continue breastfeeding the infant. A designated space for breastfeeding is essential for the caretakers and infants. A bathroom/toilet facility is not an acceptable space for designated breastfeeding. Families that require infant formula should have access to proper preparation instructions, space for bottle preparation, and access to sterilization supplies or disposable bottles and teats. Crisis communication messaging to shelter volunteers should include information about infant feeding guidelines. Infants requiring breastmilk substitutes (BMS) are at risk for food insecurity during emergencies. Therefore, all caretaker-infant dyads should receive support and assessments in sheltering and relocation locations.

Long-Term Displacement

Water and hygiene concerns are important for IYCF-E planning in long-term displacement settings. Diarrheal illnesses are the second leading cause of death of children under the age 5 (WHO 2015), and malnutrition and stunting severely impact infant health. Assessments of each mother-baby dyad to provide feeding support are essential. Relactation, cup feeding, and proper complementary feeding should all be considered when supporting families that are in long-term displacement situations. Mother-baby tent or space can provide a location for displaced families in mass-sheltering scenarios. These spaces may often overlap with other service providers such as psychosocial first aid or reproductive care and planning. Additionally, families should receive adequate age appropriate nutrition for toddlers and young children, such as whole fruits and vegetables. Beliefs, practices, and norms about infant feeding may vary across cultures and locations. Groups providing infant feeding support in emergencies should include cultural competency as a core part of their training and outreach activities. Having local community members as a part of the nutrition assessment team can build rapport with the families and create systems of capacity building (Murphy 2014) for the post-disaster recovery processes and in long-term humanitarian crises.

E

Conclusion

Implications for practice and policy: Emergency support functions should coordinate to support safe infant feeding. Specifically, mass-sheltering personnel should coordinate with nutrition and medical personnel to create consistent but flexible IYCF-E protocols. Additionally, increasing rates of baseline breastfeeding can improve health outcomes for families vulnerable to hazards and disasters. In complex humanitarian and long-term emergencies, humanitarian groups, in partnership with local governments of the affected area, should prevent mass distribution of BMS and CCF. Finally, proper steps should be taken to ensure that toddlers and small children have access to small but frequent meals that are highly nutritious.

Definition

International emergency management is a complex system that includes response and recovery efforts that take place in countries with little or unstable infrastructure and lack of consistent resources.

Introduction

In this section, an overview of concepts relevant to international emergency management will be discussed to provide a foundation for understanding how conflict, natural disasters, and climate change affect different groups of people globally. In addition, a brief description of key international organizations will be reviewed. Responding to international emergencies requires tremendous communication, coordination, and execution on every level, from local resources, to regional, to international. As the world faces the looming threat of climate change and environmental degradation as a result of human behaviors, international crises become inextricably tied to increased natural disasters, less resources, and human conflict.

In general, the international community responds to emergencies in one of two ways: refugee and non-refugee. The United Nations has two separate mechanisms for response: the Refugee Coordination Model that focuses on

responding to refugee crises and the Humanitarian or Charter Approach that focuses on non-refugee crises. For example, the war in Syria created one of the largest refugee crises of the modern era. This crisis is considered a refugee emergency, so the UNHCR is the lead agency implementing refugee coordination, support, and response following the Refugee Coordination Model (see below). An example of a non-refugee emergency is the 2018 Indonesian tsunami and earthquake.

Refugee

There are an estimated 25 million refugees. The UNHCR defines a refugee as:

> [S]omeone who has been forced to flee his or her country because of persecution, war, or violence. A refugee has a well-founded fear of persecution for reasons of race, religion, nationality, political opinion or membership in a particular social group. Most likely, they cannot return home or are afraid to do so for fear of their lives. War and ethnic, tribal and religious violence are leading causes of refugees fleeing their countries (UNHCR n.d.).

In 1951, the Geneva Convention was signed, thus providing a definition of the term "refugee" and setting the UNHCR's broad mandate including the establishment of the three durable solutions:

1. Voluntary repatriation if it is safe to return (returning home)
2. Integration in host community (staying where they initially fled to)
3. Resettlement in a third location (in a country with a resettlement program generally)

The unfortunate reality is that most refugees experience a protracted situation, and returning to their homeland is too dangerous or simply not feasible. Each State (or country) determines how it defines refugee and asylees; therefore there are several various terms of refugee and where a country will allow admittance. For example, the United States may recognize Tibetans as refugees, but China does not (see Table 1: case study of Tibetan people, Fig. 1). The rights of refugees center around five key concepts:

Non-refoulement. Under international refugee law, States are "obligated" to not "refoul," or return, a refugee to their country of origin if it is still unsafe (their safety, life, or freedom were still under threat) (1951 Convention, art. 33(2)).

Freedom of Movement. Technically, refugees should be granted the ability to live in freedom and to be able to move freely in the place they have fled.

Right to Liberty and Security of the Person. While seeking asylum, refugees have the right to be secure and be safe and the right to liberty. Many countries detain asylum seekers, so this is meant to be a protection for them.

Right to Family Life. The family is seen as the "natural and fundamental group unit of society and is entitled to protection by society and the State" (International Covenant on Civil and Political Rights, art. 23(1)). This right essentially states that refugee families should stay together.

Other Rights. The 1951 Convention also protects other rights of refugees, such as the rights to education, access to justice, employment and other fundamental freedoms, and privileges similarly enshrined in international and regional human rights treaties.

Despite these rights being protected in the 1951 Convention and under human rights treaties, refugees in various countries do not enjoy full or equal legal protection of fundamental privileges (Mincin 2012). In the next three sections, issues faced by refugees – namely, asylum, statelessness, and displacement – that directly impact on international emergency management strategies and decisions are discussed.

Asylum

For a person to claim asylum in a country outside the individual's country of origin, an asylee must prove a well-founded fear of imprisonment, torture, or threat to life if they are returned to their country of origin. Persecution may be based on things such as violence (mental or physical), legal or law enforcement punishment (1951 Convention; Council of Europe), forced participation in criminal military service, violations based on gender (or gender-based violence), etc. In addition, well-founded fear and persecution can be based on the individual's race, religion, nationality, or political opinion or

The tensions and territory and land disputes between China and Tibet have a long history dating back to the end of the British colonial rule in the eighteenth century (Hess 2009). However, in 1950, the China invaded Tibet resulting in the Tibetan leader the Dalai Lama being forced into exile by 1959 (Doshi 2017; Hess 2009). The Tibetan plateau holds vast amounts of water reserves that China can harness for energy and other resources (Doshi 2017). In addition, Tibet boarders India making the geopolitical aspect to occupying Tibet an interest to the Chinese Communist government (Doshi 2017). The Dalai Lama has yet to return to Tibet and since 1959 has been leading the Tibetan Government in Exile in Dharamsala, India. For Tibetans who remain in China, they face fierce persecution, limited autonomy (or movement), and are forbidden to practice their religion (Buddhism) or have pictures of their political and spiritual leader, the Dalai Lama. The China-Tibet conflict is often viewed as an ethnic and/or religious conflict. This is understandable, given the prominence of ethnicity and religion in the conflict. Many Tibetans are Buddhists, while ethnic Han Chinese are generally not (Hess 2009). In addition, the Chinese government has a history of persecuting religious movements, especially those which draw large numbers of followers and which have the potential to transform into political movements that could potentially threaten the regime's hold on power (Hess 2009).

The situation in Tibet remains oppressive for Tibetans who still live there as there are reports of human rights abuses and persecution (Nickerson 2018; Doshi 2017; Dolma et al. 2006; Crescenzi 2002). For Tibetans who fled their country, the situation had created a profound sense of loss of home, nationality, and cohesion as an ethnic group (Nickerson 2018). The United Nations has not yet determined Tibetans are refugees; China is a major political player in terms of security, global economy, and power (Dolma et al. 2006). While land claims continue to be debated and the appetite to challenge China on-behalf of the Tibetan people non-existent, the United States and other major country still do not officially recognize Tibet as independent; they recognize Chinese sovereignty over Tibet. Recently, India has begun to offer Tibetans living in India Indian passports and pathways to citizenship (Nickerson 2018; Doshi 2017). Returning to their homeland seems like a distant dream for Tibetans.

Additional Resources on the Tibet and Human Right

1. Tibet: The Forgotten Refugee Crisis – https://www.dailysignal.com/2015/10/23/tibet-the-forgotten-refugee-crisis/
2. BBC Tibet Profile – https://www.bbc.com/news/world-asia-pacific-16689779
3. A State within a State: Tibetans in Nepal – https://thediplomat.com/2016/07/a-state-within-a-state-tibetans-in-nepal/

For Discussion

1. Are Tibetans refugees or stateless? Why? Why not?
2. What would an international disaster response look like in this scenario? Is it a refugee-based response or a non-refugee-based response?
3. How does this differ from a United States response and recovery effort?

Emergency Management: International, Fig. 1 Case study. The Tibetan people: stateless or refugees?

membership in a particular social group. There are currently 3.1 million asylum seekers, a number far greater than the capacity for any one agency to help them (UNHCR, Figures at a Glance 2018).

Stateless

According to the UNHCR, at least ten million people worldwide have no nationality (UNHCR, Figures at a Glance 2018). Most people who are stateless are stateless through no fault of their own; they are victims of circumstance. Statelessness – not having a nationality – occurs because of discrimination against certain groups, redrawing of borders, and gaps in nationality laws. The constant in all of this is that someone without a nationality cannot live the same life as someone with a nationality. For example, if you are stateless, you cannot get an identification card or bank account, access services in most areas, travel (since you will likely not have a passport), or do things common to most people such as enroll in school since there is no proof of nationality. Imagine a lifetime of obstacles and disappointment and imagine ten million people who

cannot achieve their full potential. The international legal definition of a stateless person is set out in Article 1 of the 1954 Convention relating to the Status of Stateless Persons, which defines a stateless person as "a person who is not considered as a national by any State under the operation of its law." This means that a stateless person is someone who does not have a nationality of any country. Some people are born stateless, while others become stateless over the course of their lives.

Internally Displaced Persons (IDPs)

There are an estimated 40 million internally displaced persons (IDPs) (UNHCR, Figures at a Glance 2018). IDPs are individuals who have been forced out of/fled their community, village, or neighborhood but remain within the boundaries of their country of origin. Therefore, they remain within the "protection" of their home country but cannot return back to where they live. IDPs are considered among the most vulnerable in addition to stateless people because they lack protection from their country of origin, and yet they are under attack. Climate change, large-scale drought, and loss of livelihood as a result of climate change are some reasons, in addition to internal conflict and persecution, that affect IDPs. Agencies trying to help IDPs are overwhelmed by the combination of sheer number of people requiring aid, lack of funding, and disorganization incurred when people leave suddenly without a plan for how to survive.

International Context

The United States is a part of a global emergency management community whereby similar agreements that exist within the United States also exist internationally including mutual aid, coordinated response efforts, and short- and long-term assistance. The field of emergency management exists throughout the world with some oversight by the United Nations and key response organizations. This entry is designed to provide professionals a foundational understanding of how international emergency management functions as well as provide an overview on core concepts and systems that enable a global, humanitarian response to crises, conflict, and disasters. When considering international disaster management, it is important to understand that often response and recovery includes working in conflict areas and the aftermath of natural disasters (Collins 2018; Phillips et al. 2017). In the United States, we are more familiar with natural disasters and mass violence. For example, while the United States has high rates of gun violence, mass shootings, and riots, they are currently not on the scale of what is experienced in other parts of the world as wars are generally fought overseas. In addition, while the United States is experiencing the effects of climate change (such as more extreme weather and wildfires), other nations experience famine as a result of drought and disease outbreak in greater severity. Phillips et al. (2017) point to the 2014 Ebola outbreak as an example. Thousands of people died as a result of the 2014 Ebola outbreak primarily in Sierra Leone and Liberia. In the United States, one person died (Phillips et al. 2017).

International emergency management is implemented in times of crisis. While, at times, the international community will distinguish between a conflict response as humanitarian aid and a response to natural disasters as international emergency management response, those distinctions are fading as the emergency management community recognizes that disasters occur from both human-made and natural effects. The context may be different in Yemen than in Indonesia after a tsunami, but the emergency response needed to help people recover tends to be the same (Bullock and Haddow 2003; Phillips et al. 2017). Further, climate change is increasing the impacts of both conflict (as resources become scarcer around the world, the risk of conflict and war increases as well) and natural disasters (such as drought caused by over-farming and deforestation) (International Organization on Migration, Migration, and Climate Change n.d.). Consider the statistics. Globally, there are an estimated 68.5 million people who have been forced to flee (UNHCR, Figures at a Glance 2018), a number that has surpassed the number experienced during World War II (UNHCR, Figures at a Glance 2018). Currently, the world is seeing the largest

number of forced migrations from conflict alone. The World Bank estimates there could be 148 million climate migrates in the coming years (International Organization on Migration, Migration, and Climate Change n.d.; Parker 2018; Spiker et al. 2018).

A compelling factor in international disaster management is the fact that there are over 195 countries in the world today with 193 participating members (or member states) of the United Nations (World Atlas, How Many Countries are There in the World 2018), thus making standardization, coordination, oversight, and mandatory practice challenging. Part of understanding how international emergency management functions includes understanding the legal frameworks, working groups, and mechanisms that enable humanitarian aid to work. This includes power dynamics, inequality, and globalization and the intersection of crisis, conflict, and oppressed groups. In addition, it is important to understand the international legal definitions and frameworks that essentially enable the international disaster system to function, of which the United States is a part of. The foundation of international disaster response is the notion that all people are deserving of assistance during emergencies and crises in a dignified manner and with integrity placing the person first. According to the International Federation of Red Cross and Red Crescent, NGOs agree that humanitarian aid must be delivered to all people without impediment and that "[a]id is given regardless of the race, creed or nationality of the recipients and without adverse distinction of any kind" (DRC n.d., bullet 2). The next section describes the roles and responsibilities agencies play in international disaster management.

Agency Roles and Responsibilities

International Nonprofit Organizations/ Nongovernmental Organizations

Similar to the history of disaster response and recovery organizations in the United States, there are several international relief organizations. Some agencies are well known, such as the International Red Cross, Medecins Sans Frontieres (MSF or Doctors Without Borders), and Save the Children. Others are less known, but equally as important in terms of providing much needed assistance often in unsafe conditions. These may include Mercy Corp, Islamic Relief, and BRAC, an organization that assists with humanitarian relief as well as development. International nonprofits, also referred to as international nongovernmental organizations (INGOs), are private, nongovernmental organizations. Generally, INGOs have multiple chapters or offices throughout the world and function as a large-scale operation. INGOs are not considered local community-based organizations, though often work closely with local organizations during response and recovery. INGOs are lead organizations within the United Nations response system (see section below) and tend to have a lot of capacity and resources when it comes to logistics and person-power. For example, the MSF has a stockpile of supplies ranging from vaccines to basic food and water. This stockpile can be deployed rapidly at almost any time.

Community-Based, Faith-Based, and Ethnic-Based Community Organizations

As the name indicates, community-based organizations (CBOs) are nongovernmental, private nonprofits run locally and fully embedded in communities. Ethnic- and faith-based organizations are similar to CBOs but are primarily focused on specific ethnic or faith communities. That essentially means they are founded in a specific faith or ethnicity but may provide services outside the specific faith or ethnicity (McKnight and Plummer 2015; Phillips et al. 2017; Mincin et al. 2013). While CBOs, FBOs, and ECBOs may have less capacity in terms of funding, person-power, and resources, they are crucial partners during emergencies. CBOs/FBOs and ethnic community-based organizations (ECBOs) have deep relationships with the people in affected communities and can assist with culturally appropriate responses, emergency program planning, and implementation and assist with communications and coordination on the ground. Perhaps the most critical role CBOs and ECBOs play is in ensuring the local language, culture,

religion, and context are not only taken into account but fully integrated into every aspect of emergency response planning and relief work. Large, international organizations do make efforts at hiring people from the community in local offices; however response teams may include people from Europe and the United States. It is not enough to have cultural competence, and it may be difficult to deeply learn about and fully understand specific cultures, languages, religions, and ethnicities during rapid deployments. Working closely with and allowing local organizations and community leaders and members to take the lead in terms of response and program development and implementation is vital.

When aid workers are deployed to the Ceylanpınar refugee tent camp located in Turkey just along the Turkey/Syrian border (UNHCR 2018), it is necessary for them to understand the Syrian conflict and why so many have fled, but also to understand gender roles, the majority religion practiced, and cultural practices for Syrian and Turkish people (Phillips and Thompson 2013). It is the job of the aid worker to be as nonjudgmental and humble as possible when delivering aid in a foreign country (Phillips et al. 2017). It is only logical and correct, then, to allow local community- and faith-based leaders to lead in implementation and navigation of systems and cultures. Further, aid workers can learn from community members and leaders while on deployment. Cultural sensitivity and respect are paramount, but the willingness to be open to learning about and sharing in the experiences of the community you are working with during a response is equally as important. This informs delivery of services, ensures continuity when the response moves into the recovery phase, and assists aid works on future deployments. In the example of aid workers being deployed to Ceylanpınar, there are not only likely differences between refugees in the camp and aid workers who come from all over the globe, there are cultural practice differences between people from Turkey and Syria. One cannot simply assume that because it is the same geographic region or that there is a shared religion (as is the case for Islam) that practices and cultures are the same (Dalal 2017). In addition, within Syria, there are distinct ethnicities and religions including the Bedoin, Sunni Muslim, Shia Muslim, and Assyrian Christians (Dalal 2017; Kannike 2019).

United Nations High Commission on Refugees (UNHCR)

The UNHCR was officially established in 1950 (UNHRC n.d.), initially with a 3-year mission post-World War II. However, in 1956, Soviet forces invaded Hungary, stopping the revolution. At that time, the permanency of the UNHCR was established (UNHCR n.d.). Generally, the UNHCR oversees activities as it relates to international conflict, humanitarian aid, international emergency management response, and protections. However, there are two additional entities that oversee North Korean asylum and Palestinians receiving aid; they are the United Nations Korean Reconstruction Agency (UNKRA) and the United Nations Relief and Works Agency for Palestine Refugees in the Near East (UNRWA), respectively (UNHCR n.d.).

United Nations Office for the Coordination of Humanitarian Affairs (UNOCHA)

The UNOCHA is one of the lead coordinating agencies active in complex, global international responses. It was initially formed in 1991 to ensure coordinated, efficient, and coherent response to humanitarian crises (UNOCHA, Who We Are n.d.). OCHA:

> carries out its coordination function primarily through the IASC, which is chaired by the ERC. Participants include all humanitarian partners, from United Nations agencies, funds and programs, to the Red Cross movement and NGOs. The IASC ensures inter-agency decision-making in response to complex emergencies. These responses include needs assessments, consolidated appeals, field coordination arrangements and the development of humanitarian policies (para. 16).

OCHA provides funding, recourses, coordination, and human power in times of crisis and emergency response. It is a central international agency in terms of international disaster response.

United States Agency for International Development (USAID)

Founded by President John F. Kennedy in 1961, the USAID leads the US international humanitarian aid responses and international development initiatives. The Office of US Foreign Disaster Assistance (OFDA) is the office within USAID, which oversees the Disaster Assistance Response Team (DART). The OFDA is responsible for the deployment of resources and relief workers globally. DART can be deployed anywhere in the world including here in the United States. For example, in 2017, DARTS responded to the earthquake in Mexico and Hurricanes Irma and Maria in the United States (OFDA 2017; USAID, Caribbean Hurricanes n.d.). In the next section, an explanation of the effects of changes in both environment and climate on the role of aid workers is provided.

Environmental Degradation and the Effects of Climate Change

According to USAID, over the last 60 years, the world population went from 2.5 billion people to over seven billion, increasing the demand for ever-shrinking resources and conflicts that stem from resource control. Exacerbating the situation is the use of fossil fuels and rapid deforestation (USAID, Environment and Global Climate Change 2018). Climate change is creating more fierce and intense weather events and, as resources shrink, perpetuates wars and conflicts as people fight over control of those resources. The International Association of Emergency Managers recognizes the importance and severity of climate change. In 2015, IAEM released a statement stating:

> Ongoing climate change affects all regions, generating not only direct public-safety hazards, but also long-term economic, sociological, and public-health impacts. IAEM-USA strongly recommends comprehensive mitigation and adaptation strategies, integrated with existing processes such as hazard and land-use planning, as the only realistic path for resilience among individuals, communities, and our nation. In addition, IAEM-USA specifies that emergency managers have a critical role in this process and should be considered essential participants at all levels of government (IAEM, The Critical Role of Emergency Management in Climate Change Planning, 2015).

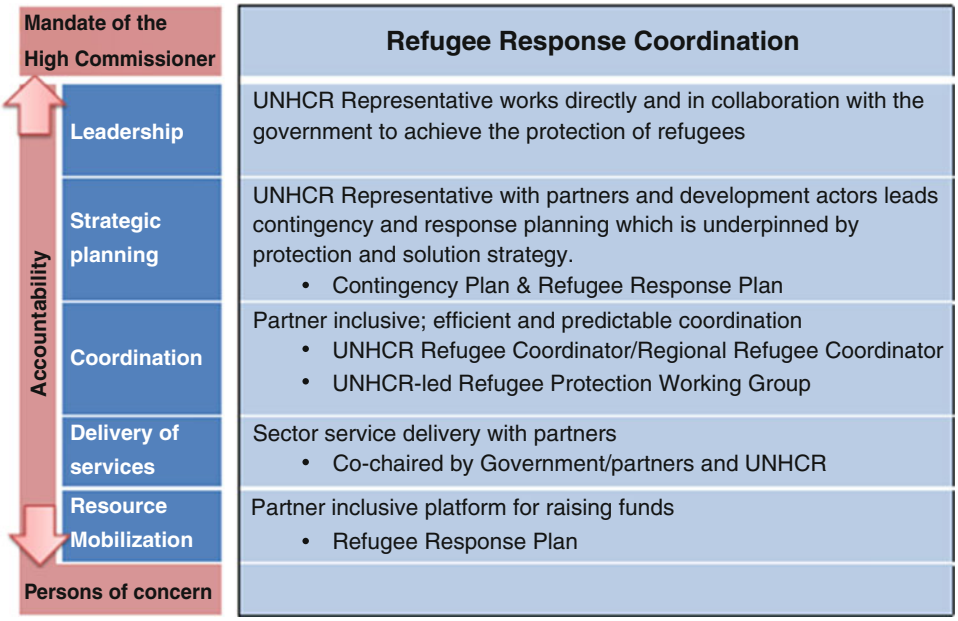
Environmental degradation and climate change have had a significant impact on migration flows, refugees, IDPs, and other vulnerable populations. This creates increased complications on humanitarian aid workers and international disaster response and recovery systems (Coppola 2015). In addition, climate change disproportionately affects the most vulnerable populations including people with disabilities, the aging, people living in poverty, women and girls, and ethnic and racial minorities (Levy and Patz 2015). Levy and Patz (2015) stated, "Environmental consequences include increased temperature, excess precipitation in some areas and drought in others, extreme weather events, and increased sea level" (p. 310).

Frameworks and Governance

This section discusses key, governing agencies active in response and recovery during humanitarian crises. Humanitarian crises may include both human-made (war, conflict, terrorism, technological) and natural (tsunamis, earthquakes, hurricanes/cyclones). UNHCR, international non-governmental organizations, and community-based organizations play a key role in coordinating response and recovery as well as planning and preparedness. In addition, and especially community-based organizations, play a pivotal role in advocacy both country-wide and internationally.

Refugee Coordination Model

Given the scope and often protracted nature of refugee crises, there is a specific system overseen by the UNHCR to facilitate response and recovery during refugee crises (the Refugee Coordination Model (RCM) shown in Fig. 2). The country or countries who are receiving refugees are called the "host country." When the host country becomes overwhelmed, the RCM and the UN High Commission on Refugees (UNHCR) will



Mandate of the High Commissioner
Persons of concern
Accountability
Refugee Response Coordination
Leadership
UNHCR Representative works directly and in collaboration with the government to achieve the protection of refugees
Strategic planning
UNHCR Representative with partners and development actors leads contingency and response planning which is underpinned by protection and solution strategy.
• Contingency Plan & Refugee Response Plan
Coordination
Partner inclusive; efficient and predictable coordination
• UNHCR Refugee Coordinator/Regional Refugee Coordinator
• UNHCR-led Refugee Protection Working Group
Delivery of services
Sector service delivery with partners
• Co-chaired by Government/partners and UNHCR
Resource Mobilization
Partner inclusive platform for raising funds
• Refugee Response Plan

Emergency Management: International, Fig. 2 Refugee response coordination

coordinate a refugee response effort. According to the UNHCR RCM, "Primary responsibility to protect refugees rests with states. Coordination of the refugee response is determined by capacity and approaches of host government and builds on resources of refugees and hosting communities" (p. 1). For example, when the war in Syria started, thousands of refugees fled. Greece became a host country. Greece tried to provide as much support to the refugees seeking safety, but because the country was deeply affected by the financial crisis of 2008, Greece was still grappling with economic instability. Eventually, UNHCR provided support along with nongovernmental agencies such as the International Rescue Committee, Save the Children, and Medecins Sans Frontieres (Doctors Without Borders).

Sphere

The *Sphere Handbook* came about as an effort to bring the humanitarian community together in terms of services, protection of refugees and displaced populations, and preservation of life and dignity. It is an attempt at standardizing practices, increasing accountability, ensuring no further harm, and monitoring and evaluating. There are several participating agencies that have dedicated ample amount of time writing, updating, and implementing the standards laid out in Sphere. However, there remain issues around implementation of the standards of practice, accountability, and consistency; it is still a critical and important document and effort. It lays the groundwork in terms of shifting how humanitarian response is done and attempts to raise the bar regarding services provided and accountability.

The Sphere Project was initiated in 1997 by a group of NGOs and helped to establish the *Humanitarian Charter and Minimum Standards in Humanitarian Response Handbook* to clarify ethical roles, responsibilities, and accountability of humanitarian aid workers and to promote set, minimum criteria that put the care and empowerment of the beneficiaries first. According to the handbook's foreword:

> The Humanitarian Charter and minimum standards will not, of course, stop humanitarian crises from happening, nor can they prevent human suffering. What they offer, however, is an opportunity for the enhancement of assistance with the aim of making a difference to the lives of people affected by disaster (Sphere 2018, p. iii).

The Sphere Project has two core beliefs: (1) people affected by crisis have a right to a life with dignity and a right to assistance during the crisis and (2) "that all possible steps should be taken to alleviate human suffering arising out of disaster or conflict" (Sphere 2018, p. 4). At the core of Sphere is the philosophy that "all people have the right to safety, security, and a life with dignity" (p. 4). The Humanitarian Charter provides the ethical and legal backdrop to the core standards and protection principles and lays out nine core standards (see Core Humanitarian Standards chart). The core standards focus on people-centered approaches and response, which is largely based on a strengths-based approach to working with clients. The strengths-based, or resiliency, approach has long been used in disaster mental health, trauma, and crisis settings. The strengths-based approach, or strengths perspective, was developed by Saleeby (1996) as a different approach from the more diagnostic model (Mattaini and Lowery 2007).

According to Saleeby (1996), the strengths-based approach developed as a technique in working with people with severe mental health conditions and has since grown to work with other vulnerable populations such as the elderly, youth at risk, and even communities. It also is closely aligned with resilience, wellness, integration, and psychosocial approaches. This approach is used in both domestic disaster response and international and can be applied in conflict zones as well as natural disaster responses. The strengths-based approach, like integration, takes the prior information a refugee brings with him or her as a part of the full intake process. Therefore, information on where the refugee has been; what he or she has been exposed to and survived, known, or understood; chronic ailments; family dimensions and dynamics; and the political and social structure of the homeland all come into relevance (Ryan et al. 2008).

Sphere also focuses on agency coordination and collaboration ensuring different organizations are working together on the ground and globally. Assessment includes standardized ways of doing on-the-ground assessments during crisis as well as pre-disaster information. In addition, standardized ways of designing programs (case management, psychosocial, health clinics, food distribution sites, shelter management, etc.) and response as well as focusing on organizational transparency and accountability are a part of the core standards. Aid worker performance is usually implemented at the individual agency level (Fig. 3).

The Cluster System and Interagency Standing Committee

Established in 1992, the IASC is an "inter-agency forum for coordination, policy development and decision-making involving the key UN and non-UN humanitarian partners" with the goal of strengthening humanitarian assistance. The Cluster System, established in 2005, is a coordination approach established by the United Nations and international nongovernmental organizations as a means of ensuring coordination and effective rapid response during emergencies, crises, and disasters. The Cluster System is activated for non-refugee crises. Within the Cluster System, there are "lead" agencies that agree to be the lead coordinators during humanitarian emergencies (see Fig. 4, "The Cluster Chart").

Globalization, Power Dynamics, and Humanitarian Aid Systems

In this section, we will have a brief discussion on the intersection of race, gender, ethnicity, poverty, and environmental degradation as it relates to humanitarian aid systems and international disaster management and relief. For example, refugees around the world are perhaps one of the most vulnerable groups because many have been forced to flee their homes, often at a moment's notice, and have been dislocated with nothing more than the clothes on their backs. Some refugees may be fortunate enough to have received an education before they were forced to flee (such as many Iraqis) or placed in refugee camps (such as some Burmese). They must fend for themselves in environments of poverty, discrimination, lack of access to healthcare and education, and by living in a refugee camp or urban environment that often

Core Humanitarian Standard • Core Humanitarian Standard • Core Humanitarian Standard • Core Humanitarian Standard •
1
Humanitarian response is appropriate and relevant.
2
Humanitarian response is effective and timely.
3
Humanitarian response strengthens local capacities and avoids negative effects.
4
Humanitarian response is based on communication, participation and feedback.
5
Complaints are welcomed and addressed.
6
Humanitarian response is coordinated and complementary.
7
Humanitarian actors continuously learn and improve.
8
Staff are supported to do their job effectively, and are treated fairly and equitably.
9
Resources are managed and used responsibly for their intended purpose.

Impartiality
Neutrality
Independence
Communities and people affected by crisis

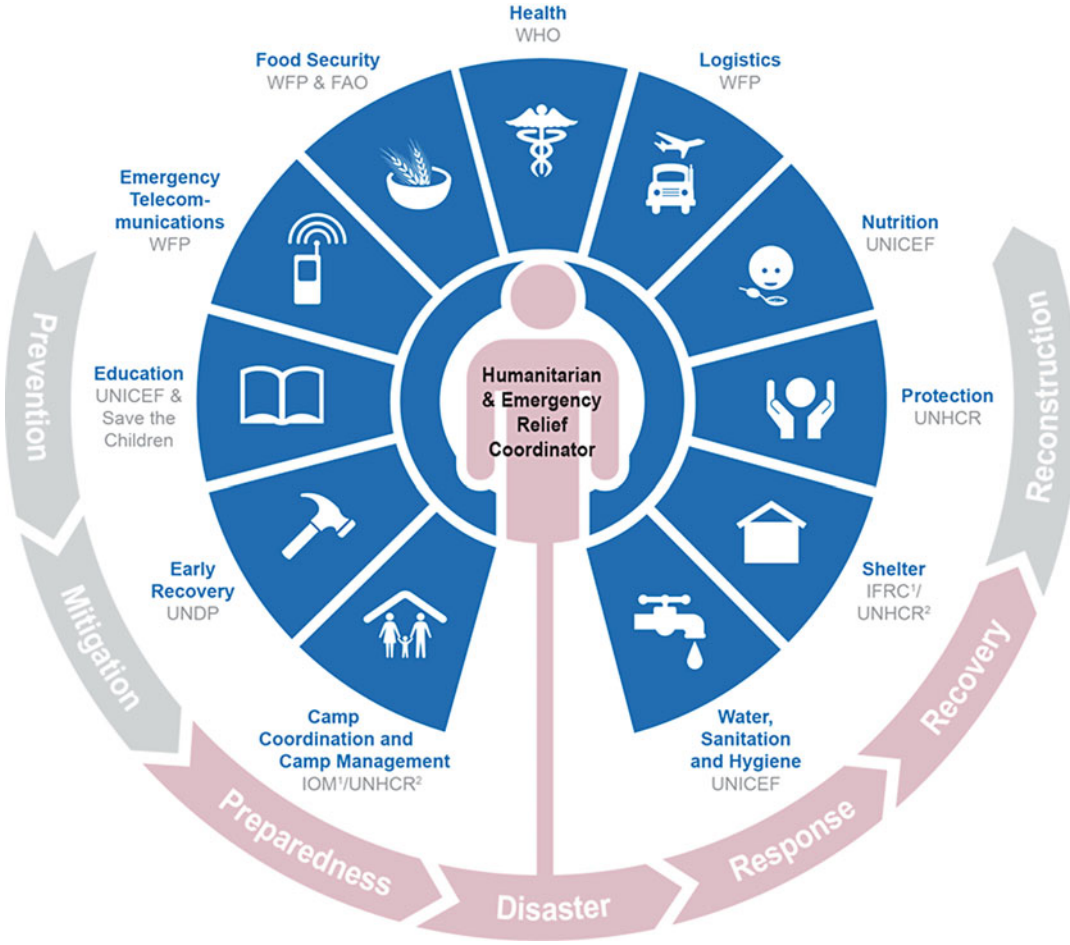
Emergency Management: International, Fig. 3 Humanitarian core standards

is not welcoming to them. Many languish in camps for years even though the refugee assistance community has learned that—once given certain opportunities—they can thrive (Mincin 2012, Mincin and Phillips 2017).

According to the Federal Emergency Management Agency's International Disaster Management, Chap. 13: International Emergency Management (2013) stated:

> The capacity to respond to large disasters achieved by individual nations can be linked to several factors, including propensity for disaster, local and regional economic resources, organization of government, and availability of technological, academic and human resources. However, it is becoming increasingly common that the response ability of individual nations is insufficient in the face of large-scale disaster, and outside assistance must be called upon. The greatest incidence of natural disasters occurs within developing countries, with 90% of disaster-related injuries and deaths sustained in countries with per-capita income levels that are below $760 per year (p. 2).

The Ebola outbreak of 2014 (see Table 2, "Case Study 2014 Ebola Outbreak", Fig. 5) is an example of how developing countries are more vulnerable and at higher risk for death and disruption from emergencies and crises. Developing countries, such as Liberia and Sierra Leone, do not have robust, functional healthcare systems, and strong infrastructure. When a crisis occurs, the response community must contend with moving materials and relief workers to the location (logistics) as well as establish relief centers. When physical infrastructure (roads, hospitals, clinics, etc.) are either not established or sparse and basic to begin with, the effects of response are immediate.



Emergency Management: International, Fig. 4 The cluster approach, IASC

Conclusion

As this entry demonstrated, international emergency response is complex due to the large number of organizations involved in several aspects of relief work. The field is vast and complex, requiring refugee humanitarian response to be coordinated by a separate UN entity. Both refugee and non-refugee emergencies require cooperation and resource sharing from government and non-government agencies. Research indicates that effective aid and long-term solutions are still inadequately resourced at a time when we face conflicts globally and climate change (Disaster and Climate Change 2019; Mahmood 2015; Ferris 2014; Harmer and Macrae 2004; Beeler 2018). Estimates for aid are staggering. For example, it is estimated that 22 million people in Yemen are in need of aid (Philip 2018); in Afghanistan about the same number of people who have been displaced from conflict have also been displaced by drought caused by climate change (Morse/IRIN 2019); and, there are over five million Syrian refugees and over six million displaced Syrians (Morse/IRIN 2019). In fact, OCHA estimates that over 135 people around the world are in need of some form of aid as a result of natural disasters, conflict and war, and the effects of climate change (OCHA 2018). Organizations writ large need to consider the complex interplay between climate change, conflict, natural disasters, poverty, race, and gender

In 2014, the world saw the largest Ebola outbreak in history (Centers for Disease Control 2017). Ebola is a deadly virus that can quickly spread via body fluids especially in conditions where communities do not have access to basic hygiene. According to a report by Save the Children, over 23,000 people contracted Ebola, and over 11,000 people died with 433 of them healthcare workers responding to the health emergency (CDC 2017; Wright and Hanna 2015). The tragedy of the Ebola outbreak was in part because of fragile health systems in West African countries as well as the international community's slower than usual response (MSF 2014; Saxene 2014). Guinea, Liberia, and Sierra Leone experienced the worst of the outbreak and were hardest hit with those infected and loss of life. As a result of the countries having weak health systems, Ebola was not contained, and the local and national response systems quickly overwhelmed (Wright and Hanna 2015). Compounding the situation is the fact that those most vulnerable and located in more remote and poor areas were hardest hit and lacked access to health services and education (Wright and Hanna 2015). In addition, women (especially pregnant women) and children were at greater risk.

Key US-based organizations assisted in the response in-country including the USAID and the CDC. In order to stem the spread of the disease, stronger surveillance systems needed to be put in place as well as in-country bolstering of healthcare workers and aid workers (CDC 2017). The USAID deployed the DART (Disaster Assistance Response Teams) in coordination with the UN and the World Health Organization (WHO). International relief organizations responded as well including the Medecins Sans Frontieres (MSF), the International Rescue Committee (IRC), and Save the Children among others. Although relief organizations alerted officials locally and internationally early on in the epidemic, the alert was not acted upon immediately according to some organizations (Gegout 2015). Among lessons learned from the response included: listen to nongovernmental organization alerts and assessments, improve health systems and facilities in-country, plan logistical responses to health emergencies better, and fund pharmaceutical research (Gegout 2015; Wright and Hanna 2015).

Additional Resources

1. Save the Children: A Wake up Call – https://www.savethechildren.org.uk/content/dam/global/reports/health-and-nutrition/a-wake-up-call.pdf
2. Key Events in the WHO Response to the Ebola outbreak – https://www.who.int/csr/disease/ebola/one-year-report/who-response/en/

For Discussion

1. What aspects of the Cluster System gets activated in this scenario?
2. What is the role of the United States? Which US agency would be the lead?
3. What type of an emergency was the Ebola Outbreak considered?
4. What key factors aided in the spread of Ebola and death toll?
5. Think about the United States role in these types of emergencies. How does mutual aid assist locally and globally? How can the United States not only assist during response but in the recovery phase as well?

Emergency Management: International, Fig. 5 Case study. 2014 Ebola outbreak

as aid workers continue to meet the growing challenges of displacement. In addition, a push toward local solutions, empowerment, and resiliency building may be a part of the solution. However, resources, support, technical training, and funding need to be made available to local community organizations.

This entry provided an overview of key response agencies, response mechanisms and systems, definitions and roles and responsibilities, and the global context. Emergency managers are encouraged to further learn about and read technical field documents offered in the resources section.

Emergency Management: Pets

Ashley K. Farmer[1] and Sarah E. DeYoung[2]

Keywords
Pets and disasters · Companion animals · Evacuation · Sheltering

Definition

The issue of emergency management and pets includes policies and research on how ownership of companion animals influences decisions in the context of disasters, including sheltering, evacuation, and re-entry considerations.

Introduction

Pet ownership affects the ways people react to and respond to disasters. These reactions include refusals to evacuate, early re-entry into closed areas to check on or retrieve pets, and psychological factors such as stress or trauma from the loss of a pet. Approximately 68% of Americans are pet owners (American Pet Products Association 2018), and therefore, the ways that pet ownership impacts evacuation and sheltering decisions during disasters remains a growing concern for emergency managers. Factors that influence the response of pet owners to disasters include attachment and commitment levels to pets, lack of proper evacuation plans, lack of available resources for transport and housing, and risk perception (Heath et al. 2001; Heath and Linnabary 2015). There are also complex issues related to the ways in which interest groups engage in decision-making to move and manage stray animals, wildlife, livestock, zoo, and research animals (Irvine 2009).

PETS Act

Pets are often considered a beloved part of families, and this is reflected not only in the passage of the PETS Act, but also in what is described as the sociozoologic scale (Arluke and Sanders 1996). This refers to the social categorization of some species as more or less deserving of attention and protection. Animals considered as pets have more value to humans, because there is often an emotional attachment and affection for the animal. With numerous images of pets left behind after Katrina, this bolstered support for the inclusion of animals in emergency management policies. After Hurricane Katrina in 2005, the issue of companion animals and disasters came to the forefront of public attention. This attention was a catalyst for the Pets Evacuation and Transportation Standards (PETS) Act (2006). Approximately 200,000 pets were abandoned or left behind during Hurricane Katrina, with just 5% of them ever reunited with owners (Lowe et al. 2009). The PETS Act requires that states include companion animals in disaster response plans in order to receive federal funding. Despite this, pet owners maintain primary responsibility for including their animals in household emergency plans. Additionally, shelters are not required to accept pets. The goal of this legislation was to provide additional resources to encourage evacuation compliance.

Evacuation and Sheltering

Households with pets are less likely to evacuate (Day 2017; Heath et al. 2001). Pets are often considered a part of the family, and many will refuse to leave if they cannot bring companion

animals along with them (Farmer et al. 2017; Leonard and Scammon 2007). In one study, respondents who owned pets were 52% more likely to choose to not evacuate (Petrolia and Bhattacharjee 2010). Weaker human-animal bonds have been associated with leaving pets behind, so the less attached one is to their pet the less likely it is they will evacuate their pets (Heath et al. 2001). Additionally, regular vet visits are associated with stronger attachment to companion animals. These pet owners are also more likely to include pets in disaster plans, suggesting that failure to evacuate with pets means there is a weaker bond and/or lower standard of care (Heath et al. 2001). One study found that low-income residents were more likely to leave animals behind during disaster events (Hesterberg et al. 2012), suggesting that access to resources is linked with ability to bring animals to the sheltering destination. Power structures and policies may also play a role in facilitating the evacuees' ability to bring their animals during an evacuation. For example, stories emerged after Hurricane Katrina that described owners who were forced to evacuate without their pets by first responders (Irvine 2009). Therefore, pet attachment and bonding are not the only factors in predicting the success of evacuation compliance.

Residents also might refuse to evacuate because they do not know where to take their pets, local shelters might not accept pets, or they cannot find information on pet-friendly shelters. Rumoring surrounding pets and proper evacuation protocols were evident during Hurricane Harvey and Irma (Federal Emergency Management Agency 2017). If leaving pets behind is not an option, residents will often stay behind with them if they cannot make other accommodations for animals. Pet owners who do evacuate are less likely to stay in a motel, hotel, or emergency shelter because those places lack pet accommodations or do not accept pets (Whitehead et al. 2000). A separate issue is that if residents evacuate quickly and leave pets behind, there is a possibility they will attempt to return early for their pets, which puts them in danger (Heath et al. 2001). This is more likely for a quick-onset disaster, where supplies are not readily prepared or available, and residents must leave immediately and do not have time to retrieve their pets.

Social Media and Reunification

There are also unexpected scenarios that might happen, including a pet becoming lost or running away during the evacuation or sheltering process, and they are separated from their owner. Reunification plans can become problematic if pets are not microchipped or do not have on identification tags. In the aftermath of recent hurricanes (e.g., Hurricanes Matthew, Harvey, and Irma), social media groups have been created with the aim of reuniting lost pets with owners (DeYoung and Farmer 2018). These groups have also publicized information about pet-friendly shelters, where individuals can go to volunteer help, and any animals that are in distress or need to be rescued.

Logistics and Planning

Other concerns have emerged about logistics of evacuating with companion animals (Farmer et al. 2017). Many supplies are needed for evacuating with pets, such as food, bowls, leashes, and carriers, and making sure there is room to bring pets. This can become a hassle for residents because traveling with pets is not an easy task. Additionally, they might be concerned about where to find pet friendly shelters or hotels. Those who do bring pets along might have to travel long distances to find accommodating hotels. Additionally, this can bring added stress for the animals themselves, as they are in unfamiliar locations and also dealing with the trauma of evacuation during a disaster. This can lead to some behavior changes in pets and ultimately create additional stressors or problems for their owners (DeYoung and Farmer 2018).

Conclusion

Emergency preparedness should continue to be integrated with pet ownership. This includes

helping individual households make emergency plans that include pets, widely disseminating information about pet friendly shelters, and state and local emergency managers effectively giving information to the public (Farmer et al. 2017). Companion animals are vulnerable during disasters because of their dependence on people (Bankoff 2014). Owning pets also increases risk for humans, since pet ownership has been linked to refusal to evacuate (Whitehead et al. 2000). Policies that continue to encourage emergency plans that include pets and state level planning for pet friendly shelters would ultimately increase evacuation compliance. Ultimately, the ownership of companion animals is connected to pre- and postdisaster decision-making processes.

Emergency Management: Preparedness and Planning

David A. McEntire
College of Health and Public Service, Utah Valley University, Orem, UT, USA

Keywords

Capacity building · Emergency operation plan · Preparedness · Planning

Definition

Preparedness is a broad, encompassing concept in emergency management that "involves anticipatory measures taken to increase response and recovery capabilities" (McEntire and Myers 2004, p. 141). A component of preparedness in emergency management is planning, which is defined as the "logical and analytical problem-solving process to help address the complexity and uncertainty inherent in potential hazards and threats" (FEMA 2010, pp. 1–3).

Introduction

Preparedness and planning in daily life imply getting ready for something of significance that is anticipated to take place or occur in the future. In emergency management and homeland security, preparedness and planning have a similar connotation, but mainly deal with efforts to help individuals, organizations, communities, and even the nation to anticipate and cope with emergencies, terrorist attacks, and disasters (see ▶ "Emergency Management: Crisis Management and Response" in this encyclopedia). In this sense, preparedness and planning are concepts and activities that are often closely related and convoluted, but they are not always or entirely synonymous.

Preparedness is a broader, more encompassing concept that is comparable to other phases/functions of emergency management (e.g., mitigation, response, and recovery) as well as the phases/functions of homeland security (e.g., prevention and protection). For instance, mitigation and preparedness occur before a disaster like prevention and protection, although mitigation is concerned about the reduction of risk and impacts, whereas preparedness assumes disasters and attacks will occur. In addition, preparedness is related to response and recovery since it is believed to improve operations in the aftermath of all types of emergencies, terrorist attacks, and disasters (see ▶ "Emergency Management: Crisis Management and Response" in this encyclopedia).

In contrast to preparedness, the term planning is often considered a subset or very specific type of action under the function of preparedness. As an example, planning includes a projection of what disasters may occur and a description of what should be done to react to such hazards, threats, and vulnerabilities. Thus, both preparedness and planning capture efforts to improve readiness to deal with emergencies, disasters, terrorist attacks, and their specific consequences. The nature of preparedness and planning will be discussed further with specific examples of each type of activity.

Understanding Preparedness

Views about preparedness vary slightly among emergency management and homeland security institutions/practitioners and the scholars who study disasters. And, this concept is not always used consistently within organizations or by individuals. For instance, the Federal Emergency Management Agency (FEMA. 2019a) defines preparedness as a "continuous cycle of planning, organizing, training, equipping, exercising, evaluating, and taking corrective action in an effort to ensure effective coordination during incident response" (p. 1). However, FEMA (2015) also purports that preparedness is an overarching effort that captures all aspects of emergency management and homeland security. As an example, in its National Preparedness Goal, FEMA notes the priority of developing "a secure and resilient national with the capabilities required across the whole community to prevent, protect against, mitigate, respond to, and recover from the threats and hazards that pose the greatest risk" (FEMA 2015, p. 1).

FEMA has likewise created a National Preparedness System that entails six major priorities: identifying and assessing risk, estimating capability requirements, building and sustaining capabilities, planning to deliver capabilities, validating capabilities, and reviewing and updating (FEMA 2019b). These priorities have the goal of helping the nation anticipate disasters and effectively respond when they occur. Examples of each priority are mentioned below.

Priorities	Example
Identifying and assessing risk	Determining if an earthquake could occur and what the impacts will be
Estimating capability requirements	Making educated guesses about the need for rescue operations, fire suppression, and emergency medical care
Building and sustaining capabilities	Purchasing fire apparatus, extraction equipment, and medical supplies
Planning to deliver capabilities	Training with apparatus, equipment, and supplies
Validating capabilities	Completing a disaster exercise
Reviewing and updating	Learning from exercise and replacing old equipment

In addition to the 6 major priorities, FEMA has identified 32 core capabilities in its National Preparedness Goal (2019c). While the priorities are meant to improve preparedness processes, these core capabilities suggest ways to improve the performance of typical functions in a disaster. They include:

- Planning
- Public information and warning
- Operational coordination
- Forensics and attribution
- Intelligence and information sharing
- Interdiction and disruption
- Screening, search, and detection
- Access control and identity verification
- Cybersecurity
- Physical protective measures
- Risk management for protection programs and activities
- Supply chain integrity and security
- Community resilience
- Long-term vulnerability reduction
- Risk and disaster resilience assessment
- Threats and hazards identification
- Critical transportation
- Environmental response/health safety
- Fatality management services

As can be seen, FEMA's view of preparedness is extensive and closely tied to terrorism and homeland security since it concentrates on activities such as forensics, intelligence, interdiction, screening, access control, cybersecurity, protective measures, etc. FEMA also suggests that preparedness is what a community, state, or nation does to build capacity to address all types of emergency management/homeland security functions. Capacity building implies "an ongoing process that equips officials, stakeholders and the community to perform their functions in a better manner during a crisis/disaster" (NDMA 2019).

Like their counterparts in emergency management and homeland security, professors and researchers also see preparedness as a foundational principle in these important areas (Kreps 1991, p. 31). However, scholars are more likely to consider preparedness in a slightly narrower fashion than does FEMA, mainly concentrating on what is done in advance of a disaster to get the community ready to react in an effective and efficient manner. For instance, Godschalk (1991) views preparedness as "actions taken in advance of an emergency to develop operational capabilities and to facilitate an effective response in the event an emergency occurs" (p. 136). McEntire and Myers (2004) assert that preparedness "involves anticipatory measures taken to increase response and recovery capabilities" (p. 141).

Under this academic perspective, mitigation does not generally fall under the concept of preparedness. Instead, mitigation is concerned more about disaster prevention, while preparedness is more focused on readiness for disasters. Therefore, scholars believe mitigation and preparedness have different assumptions (e.g., mitigation assumes disaster prevention or reduction is possible, while preparedness assumes a disaster will occur and that response and recovery will therefore be necessary).

Although FEMA and scholars view preparedness differently, there are still considerable similarities between the professionals and scholars who are involved with disasters, emergency management, and homeland security. Both groups view preparedness as a major priority to successfully anticipate contingencies and make improvements on how best to react to them.

Specific Preparedness Activities

Preparedness in emergency management and homeland security is multifaceted and quite complex. For example, Mileti (1991) stated that "the purpose of preparedness is to anticipate problems in disasters so that ways can be devised to address the problems effectively and so that the resources needed for an effective response are in place before-hand" (p. 215). He further elaborated that "preparedness includes such activities as formulating, testing, and exercising disaster plans; providing training for disaster responders and the general public; and communicating with the public and others about disaster vulnerability and what to do to reduce it" (p. 215).

In similar fashion, Gillespie and Streeter (1987, p. 155) asserted that preparedness includes planning, resource identification, the development of warning systems, training and simulations, and other pre-disaster actions taken for the sole intent of improving the safety and effectiveness of a community's response during a disaster. Preparedness therefore includes a plethora of activities, which may also include:

- Legislative mandates and organizational creation (e.g., the establishment of laws pertaining to disasters and terrorist attacks)
- Resource identification, budget acquisition, and grant management (e.g., obtaining equipment and personnel and allocating and spending funds to reach emergency management and homeland security goals)
- Risk assessment (e.g., identifying anticipated hazards, threats, and vulnerabilities)
- Planning (which will be discussed further below)
- Organizational structures that facilitate operations (e.g., establishing an emergency operations center, an incident command structure, and mutual aid agreements)
- Warning system development (e.g., establishing policy and acquiring technology to notify people in advance or provide updates as needed after the event)
- Training (e.g., teaching employees in official capacities about the plan and their role in emergency management and homeland security)
- Exercising (e.g., determining the level of understanding of the plan and ability to fulfill required tasks)
- Community education (e.g., ensuring that the public understands what can be done in advance of a disaster or terrorist attack and how they should react if such events occur)

Because there are so many features of preparedness, it is often difficult to know the true state of readiness. A city may have exceptionally detailed ordinances, but neglect to adequately fund the emergency management organization. An emergency manager may focus heavily on risk assessment, but fail to develop or adequately update comprehensive disaster plans. A fire department may spend considerable time training fire fighters on fire suppression, but not give enough attention to public education about the importance of the installation of smoke detectors in residential or commercial buildings. A community may be ready to deal with a hurricane, but could be less capable of dealing with a pandemic or terrorist attack. For this reason, preparedness is likely to be incomplete and must be seen as an ongoing process rather than a simple checklist to be completed.

Understanding Planning

Disaster planning is not interpreted or understood in the same way for different people and organizations, and like preparedness, there is no single agreed-upon definition. Nevertheless, disaster planning is often related to the creation of "systematic procedures that clearly detail what needs to be done, how, when, and by whom before . . . an anticipated disastrous event occurs" (Businessdictionary.com 2019, para 1). Relevant to this discussion is the Emergency Operations Plan (EOP), "a document that describes how the jurisdiction might respond to a disaster" (McEntire 2015, p. 131).

As noted above, planning is one of several different aspects of preparedness – although it should be pointed out that planning is one of the most well-known and essential elements of preparing for all types of disasters and terrorist attacks.

There are several key principles associated with this important concept:

1. Planning entails an identification of what types of emergencies, disasters, and terrorist attacks may occur. This may include natural, technological, and civil hazards of all categories and scope.
2. Planning also includes an anticipation of the consequences of such events. The impacts may vary from injuries, death, property destruction, and social disruption.
3. Planning involves all key participants and clarifies what will be done and who will do it. The goal is to specify who is responsible for each area or activity and how individuals and agencies will coordinate with others.
4. Planning almost always refers to the creation of a written document that describes what the organization or community will do in the case of an emergency, terrorist attack, or disaster. This document is known as an Emergency Operations Plan (EOP). It is typically made up of the basic plan (a general overview), annexes (which can be hazard-specific or functional), and appendices (such as supporting documents, standard operating procedures, maps, resource lists, etc.).
5. Planning must be based on accurate assumptions (Dynes 1994). It is important to understand how people will react in disasters, rather than assume incorrect behaviors and create plans with mistaken expectations.
6. Planning should never be considered complete or a silver bullet. Auf der Heide warns against the "paper plan syndrome" by explaining that "written plans indeed are very important, but they are only one of the necessary requirements . . . . A written plan can be an illusion of preparedness if the other requirements are neglected" (1989, p. 34).

Despite these key principles, planning may take different forms. While there is no universal standard for disaster planning, most EOPs do contain various sections including descriptions about authority, purpose, situation and assumptions, concept of operations, organization and assignment of responsibility, direction and control, plan development/maintenance, and implementation. FEMA (2010) has also provided several recommendations for communities in its Comprehensive Planning Guide 101. This document "provides methods for planners to:

- Conduct community-based planning that engages the whole community by using a planning process that represents the actual population in the community and involves community leaders and the private sector in the planning process.
- Ensure plans are development through an analysis of risk.
- Identify operational assumptions and resource demands.
- Prioritize plans and planning efforts to support their seamless transition from development to execution for any threat or hazard.
- Integrate and synchronize efforts across all levels of government" (FEMA 2010, i).

CPG 101 therefore provides recommendations on the basics of planning, the context of planning (e.g., federal, state, and local environment), the format of plans, the planning process, etc. It is a useful guide to help emergency managers meet federal planning expectations.

Specific Planning Activities

The activities subsumed under the label of planning are almost endless. However, there are four main themes prevalent in the literature. First, planning focuses on different types of disasters (e.g., earthquakes, hurricanes, flooding, tornadoes, dam failures, fires, climate change, pandemics, nuclear accidents, chemical spills, terrorist attacks, etc.). Second, planning concentrates on diverse functions that must be performed during or after a disaster (e.g., hazard detection, warning, evacuation, sheltering, search and rescue, triage and medical care, mass fatality management, stress management/mental health, public information/social media, donations management, volunteer management, damage assessment, disaster declarations, debris

management, disaster assistance, communications and coordination, decision-making, transportation and logistics, organizational continuity, rebuilding, etc.). Third, planning identifies the needs of special individuals and groups (e.g., gender, race, poor, tourists, the elderly/nursing home residents, children, the disabled, hospital patients, tribal communities, animals, etc.). Finally, planning gives attention to unique situations or locations (e.g., civil disturbances, parades, major sporting events like the Super Bowl, a Presidential inauguration, day care centers, libraries, museums, airports, hospitals, schools/universities, the workplace, water/waste water facilities, power plants, farms/food processing plants, government buildings/courts, small cities/large cities, rural communities/urban communities, etc.).

As noted, the important priority of planning is to make sure the community is considering all types of eventualities and that its pre-disaster efforts do not end with the creation of an Emergency Operations Plan (EOP) but rather pursue the goal of building capabilities. As noted earlier, building capabilities may be defined as creating the ability to successfully implement the plan. This is important since planning is incomplete in and of itself. As an example, the city of New Orleans had a very comprehensive Emergency Operations Plan prior to Hurricane Katrina which clearly detailed the potential for a hurricane and flooding, the need for evacuation and sheltering, and how to care for anticipated victims. Unfortunately, the jurisdiction was unable to implement the plan effectively (e.g., evacuate citizens by school bus, provide enough resources at the Superdome, etc.). Government leaders in New Orleans had a very detailed EOP, but unfortunately lacked the ability to implement the plan.

The Benefit of Preparedness and Planning

Virtually everyone agrees that preparedness and planning have a positive impact on response and recovery operations. Effective preparedness and planning may:

- Identify resources for response and recovery (Auf der Heide 1989, p. 39)
- Improve personal relationships among those working in emergency management (Dynes 1994, p. 147)
- Increase interorganizational coordination (Auf der Heide 1989, p. 39)
- Facilitate improvisations (Kreps 1991, p. 34)
- "Help save lives, reduce injuries, limit property damage, and minimize all sort of disruptions that disasters cause" (Mileti 1991, p. 239)

Consequently, preparedness and planning are some of the most important aspects of emergency management and homeland security (McEntire 2015).

Conclusion: Future Preparedness and Planning Needs

Preparedness and planning are vital components of emergency management and homeland security. Both deal with efforts to increase readiness for disasters and terrorist attacks. However, preparedness is a broader concept that covers many actions, while planning is one specific type of preparedness initiative that often focuses on developing an Emergency Operations Plan.

While much is known about preparedness and planning, more research is required. In spite of thousands of citations in the literature, there is still insufficient agreement on the best way to promote these key principles in emergency management and homeland security. For instance, what can be done to help communities prepare for disasters when these events are considered to be unlikely or viewed as being beyond human efforts of intervention? Are certain planning templates and processes more effective than others? Which ones and why? (See ▶ "Emergency Management: Best Practices" in this encyclopedia.) Not enough is known about what constitutes an effective plan, and there is insufficient empirical research (as opposed to anecdotal studies) on this subject.

Furthermore, additional emphasis on preparedness should be given in order to increase response and recovery capabilities of individuals, organizations, and governments. Too often people and institutions assume they are prepared because they have

a plan (i.e., the paper plan syndrome). Finally, more education and training on planning are also necessary. Emergency managers do have knowledge about planning, but their level of expertise could be expanded and deepened.

Definition

Emergency management is the managerial function charged with creating the framework within which communities reduce vulnerability to hazards and cope with disasters. Particularly, emergency management encompasses preparedness, planning, response, recovery, and mitigation of hazards and threats.

Introduction

Emergency management organizations protect communities by coordinating and integrating all activities necessary to build, sustain, and improve the capability to mitigate against, prepare for, respond to, and recover from threatened or actual natural disasters, acts of terrorism, or other man-made disasters. These organizations offer a wide array of services that enable them to handle a broad range of negative events (i.e., hazards and disasters). The Federal Emergency Management Agency (FEMA 2018), under the auspices of the Department of Homeland Security since 2003, functions as our nation's emergency manager to train our first responders to be prepared and provide security, handle a variety of hazards and threats, and help communities "before, during, and after disasters" (see entry entitled ▶ "Federal Emergency Management Agency" in this encyclopedia).

This entry focuses on the legislative (e.g., laws, acts, policies) and procedural impact of six events based on aftermath reports to improve all phases – planning, preparedness, recovery, and responses – of emergency management. Aftermath reports have been the main source for determining the strengths and weaknesses of the current emergency plans on a community's citizen health, psychological well-being, and resilience. This entry focuses on six events discussed in historical order – September 11 (2001), Hurricane Katrina (2006), Department of Defense Cyber Attacks (2008), Deepwater Horizon Oil Spill (2010), Hurricane Sandy (2012), and Oso Landslide (2014).

September 11 Terrorist Attacks

The terrorist attacks that took place in New York, Pennsylvania, and Washington D.C. on September 11, 2001, led to changes in both legislation and procedure. First, the Homeland Security Act of 2002 (see entry in ▶ "Homeland Security Act of 2002") was created to protect the nation from terrorism. Second, the Federal Emergency Management Agency (FEMA) initiated a Federal Response Plan (Public Law 93-288) to coordinate natural disasters (e.g., hurricanes, floods, fires) and technological emergency situations (e.g., radiological or hazardous materials) by mobilizing resources and augment response efforts. Third, FEMA (2004) provided its recommendations for coordinating emergency and disaster procedures by first responders under National Incident Management System (NIMS).

Subsequently, the 9/11 Commission Act (2007) addressed a wide range of DHS's missions, including critical infrastructure protection, grant administration, intelligence and information sharing, privacy, and transportation security, including aviation and bus transportation. The Act led to amendments in Section 1016 of the Intelligence Reform and Terrorism Prevention Act (IRTPA), expanded and refined the scope of the Information Sharing Environment (ISE) of the Homeland Security Act of 2002, and established guidelines for fusion centers (Homeland Security Digital Library 2017). This Act also determined fair distribution of Homeland Security grants, with over 90% of these grants allocated on a risk-based basis; required screening of ALL cargo that was being transported by passenger airplanes with limited exceptions; allotted $4 billion in grants to upgrade and implement security measures in rail, transit, and buses; and provided lawful protection of citizens who, in good faith, reported alleged or suspected terrorist activity on buses, trains, or airplanes.

Hurricane Katrina (2006)

Although Hurricane Katrina occurred in 2006, this devastating natural disaster left lasting effects

and changes in the field. This disaster most notably tested the performance of the Federal Emergency Management Agency (FEMA), which was integrated into the Department of Homeland Security (DHS) in 2003, just 3 years prior. At the time, Hurricane Katrina was the most significant disaster that FEMA faced since being absorbed by DHS. From the moment that Hurricane Katrina was determined to be a major threat to, specifically, the Gulf Coast and the City of New Orleans, there were issues and incompetence in both the federal agencies and the local responders regarding communication, planning, evacuation, and sheltering arose. As a whole, the effects and shortcomings that were seen during Hurricane Katrina helped FEMA and DHS to identify and address these shortcomings to better prepare for future disasters and events.

Hurricane Katrina had a significant impact on legislation through the development of the PETS Act of 2006, the Katrina Emergency Assistance Act, and Public Law 109-295. The Pets Evacuation and Transportation Standards (PETS) Act of 2006 amended the Robert T. Stafford Disaster Relief and Emergency Assistance Act ("The Stafford Act") to require the Director of FEMA to ensure that state and local emergency preparedness operational plans address the needs of individuals with household pets or service animals prior to, during, and following a major disaster or emergency.

The Katrina Emergency Assistance Act of 2006 also directed the President to make unemployment assistance available to individuals eligible for such assistance under the Stafford Act as a result of a disaster declaration made for Hurricanes Katrina or Rita on or after August 29, 2005, and for 39 weeks after the declaration date. This act was particularly impactful because the basis of this act has been adopted and specifically adapted for nearly every major disaster since Hurricane Katrina, to ensure that victims of disasters receive assistance required after a major disaster.

Public Law 109-295 of the Department of Homeland Security Appropriations Act of 2007 is the Post-Katrina Emergency Management Reform Act of 2006 (PKEMRA). This act "provided important provisions, including the key principle that after a major disaster or emergency declaration accelerated Federal assistance could be sent by FEMA, in the absence of a specific request by a State, to save lives and prevent suffering." Essentially, this act helped shortcomings that were brought to attention by Hurricane Katrina. The PKEMRA also established the following: Disability Coordinator; the National Emergency Family Registry and Locator System; better evacuation processes and recovery efforts following major disasters; improved transportation assistance for evacuation efforts and returning individuals to their homes following a major disaster; and case management assistance for survivors who claim unmet needs after a disaster.

2008 Department of Defense Cyber Attacks

In 2008, an infected flash drive was inserted into a military laptop from a base in the Middle East and launched the most impactful cyberattack that the US military had ever encountered. The overall goal of the attack was to infiltrate the classified systems and files on the laptop and remotely relay the information back to the owner of the flash drive, who was unknown at the time. While this particular cyberattack on the US military and its defense systems was unsuccessful, it reversed many instabilities in the United States and the military's cyber security and response efforts.

As a result of this attack, the Pentagon updated their layered defense networks built around military and high-profile networks, all of which were at risk. Additionally, the United States Cyber Command was implemented. According to a 2013 fact sheet published by the US Cyber Command's Public Affairs Office, the United States Cyber Command "plans, coordinates, integrates, synchronizes and conducts activities to: direct the operations and defense of specified Department of Defense information networks and; prepare to, and when directed, conduct full spectrum military cyberspace operations in order to enable actions in all domains, ensure US/Allied freedom of action in cyberspace and deny the

same to our adversaries." The United States Cyber Command is tasked with centralizing command of cyberspace operations, strengthening DoD cyberspace capabilities, and integrating and bolstering DoD's cyber expertise. This particular attack also began discussions between the US military, federal government, and other agencies about what the widespread response and plan was in the event of a cyberattack in any sector of the military, government, or other agencies.

While there were many preventative defense procedures and mitigation techniques that stemmed from this attack, there were few legislative acts passed and implemented as a result. Most legislation has occurred within specific governmental organizations, with new rules and policies implemented agency-wide in various agencies in order to prevent another attack of this kind and caliber from occurring again in the United States. Additionally, there have been various legislatures passed as a result of the formation of the United States Cyber Command; however, there is no direct, stated influence from the 2008 cyberattacks for this legislature.

Deepwater Horizon Oil Spill (2010)

On April 20, 2010, the oil drilling rig "Deepwater Horizon," operating in the Macondo Prospect in the Gulf of Mexico, exploded and sank resulting in the death of 11 workers on the Deepwater Horizon and the largest spill of oil in the history of marine oil drilling operations. The Deepwater Horizon Oil Spill was one of the first major environmental disasters that the United States had ever faced and was one of the most environmentally damaging. In addition to the 11 deaths as a result of this disaster, wildlife and marine life were damaged by the four million barrels of oil that flowed into the ocean over an 87-day period.

In the moments after the initial explosion which caused the dispersion of the vast amounts of oil, communications between British Petroleum (BP), the company responsible for the spill, the National Oceanic and Atmospheric Administration (NOAA), and emergency responders were extremely weak and ultimately hindered rescue, cleanup, and recovery efforts. This resulted in a reform of communication strategies between private companies, national and federal agencies, and programs, in the event of a similar emergency or disaster in the future. Additionally, this event also identified weak points in the recovery efforts of environmental disasters which are far less likely to occur than naturally occurring disasters. Because limited information exists on oceanic oil spills or their effects on ecosystems and wildlife, human health, and the economy, emergency management agencies were made aware that more thorough incident training for emergencies that are extremely unlikely but highly dangerous events must be integrated into current plans and procedures, for both preparation and response.

Because of its massive impact on the oil drilling industry, local wildlife and oceans, and the threat of another similar event occurring, the Deepwater Horizon Oil Spill led to the passing and implementation of many drilling regulations in the United States. In addition to these regulations, which helped ensure the safety and security of drilling sites and rigs, multiple agencies were formed as a direct result of the Deepwater Horizon Oil Spill. While there were many regulations and agencies formed and implemented as a result of this disaster, there are a lack of publications regarding laws and legislature passed as a direct result of this event.

The Bureau of Safety and Environment Enforcement (BSEE) was established by Secretarial Order 3299 as a direct response to the failures of the Minerals Management Service (MSS) in response to the Deepwater Horizon Oil Spill. Order 3299 also created the Bureau of Ocean Energy Management (BOEM) and the Office of Natural Resources Revenue (ONRR), all integrated into the Department of the Interior. The missions of these three entities are to ensure the balance and responsible development of energy resources on the outer continental shelf, where offshore drilling and other potentially harmful activities occur; ensure safe and environmentally responsible exploration and production while enforcing applicable rules and regulations; and ensure a fair return to the taxpayer from offshore royalty and revenue collection and disbursement activities.

Hurricane Sandy (2012)

Hurricane Sandy, which occurred from October 22, 2012, to November 2, 2012, was the largest Atlantic hurricane on record and severely impacted the states of New Jersey and New York. Damage caused as a direct result of this disaster was vast. Seventy-one people died from the hurricane, while a total of $65 million in damages. As the fourth costliest hurricane in the history of the United States, Hurricane Sandy tested FEMA and other agencies tasked with emergency management, preparedness, and management responsibilities, many of which had dealt with the fallout of Hurricane Katrina as well. Their role in Hurricane Katrina gave many agencies the insight and information needed in order to deal with many aspects of this hurricane differently than Katrina was handled.

Regarding legislation, two major bills passed in the wake of Hurricane Sandy – the Disaster Relief Appropriations Act (2013) and the Hurricane Sandy Relief Bill. The Disaster Relief Appropriations Act authorized a grant of $60 billion to be distributed to 21 different disaster relief agencies, including FEMA, the Department of Homeland Security, and the Army Corps of Engineers. The Hurricane Sandy Relief Bill amended the National Flood Insurance Act of 1968 to increase the total federal borrowing authority for the National Flood Insurance Program from $20.725 billion to $30.425 billion (a $9.7 billion difference).

Oso Landslide (2014)

A large landslide occurred in northwest Washington state on March 22, 2014, leading to tragic loss of life and destruction of property. Landslide debris covered approximately 40 homes and other structures as well as nearly a mile of State Route 530. It also caused 43 fatalities in the community of Steelhead Haven near Oso, Washington. The main impact that the Oso Landslide had on emergency management was the importance of communication and transparency between government officials, private industry, and citizens. In the years leading to the Oso landslide, it was reported that government officials knew that extensive logging in the Oso area was diminishing the structural integrity of the mountains in Oso and the public was not informed. Many citizens lived in the high-risk zone for landslides in the area, but they were never made aware until after the landslide occurred. Because of this, communication and transparency between government officials and citizens have been at the forefront for planning and emergency management efforts to date.

Because of the sheer disregard of warning signs and public communication by local and government officials that took place in regard to the Oso Landslide, the National Landslide Preparedness Act was introduced and implemented in 2017 and is currently waiting amendment. By enacting this bill, a new step toward preparedness will be taken to ensure protection of life and property in an event comparable to the Oso Landslide. The National Landslide Preparedness Act directs the US Geological Survey (USGS) to establish a National Landslide Hazards Reduction Program to identify and understand landslide hazards and risks, reduce losses from landslides, protect communities at risk of landslide hazards, and improve communication and emergency preparedness and establishes the Interagency Coordinating Committee on Landslide Hazards to oversee the program.

With advancements in technology, concomitant improvements have occurred in the way that geologists and scientists are able to predict events that would exist in such a scale, as the Oso Landslide did. There have also been major policy overhauls in areas that are known to have the same geographical makeup as Steelhead Haven and are at risk for similar types of events.

Conclusion

While every highlighted event in this entry varied from the type of event to the severity, every event helped emergency management agencies

understand the improvements that needed to be made to legislation, response, recovery, and preparedness. Many events, such as Hurricane Katrina and the Oso Landslide, caused a reaction from legislators, which sparked an increase in disaster preparedness and response and emergency management legislature. Other events, such as the 2009 Department of Defense Cyber Attacks and the Deepwater Horizon Oil Spill, ushered in new conversations about potentially targeted areas, such as cyberspace and the natural environment. Every event highlighted in this entry helped initiate a change for emergency management and response legislature and increased communication about how it can be improved. The changes that have been made as a result of these events have been successful and positive, and the future of successful emergency management lies in the ability to understand the changes that need to be made and change them.

Emergency Management: Recovery

Paolo Cavaliere
University of Delaware, Newark, DE, USA

Keywords
Emergency management · Recovery · Business recovery · Housing

Definition

Disaster recovery is the set of coordinated activities through which public agencies, nonprofit organizations, private sector, and communities work together in order to rebuild and restore

normal conditions after disasters. Recovery strategies encompass practices and actions that aim to restore the social, infrastructural, and economic fabric of communities.

Introduction

During the last decade, humanity has witnessed an increased number of deadly events. Only for weather-related events, NOAA reports a number of 108 events with an economic impact of $725 billion. (Billion-Dollar Weather and Climate Disasters: Summary Stats. https://www.ncdc.noaa.gov/billions/summary-stats.) Tropical cyclones account for a 56% of the overall loss. Besides the American situation, the impact on communities and the overall economic costs after disasters is a burden that governments attempt to lighten, adopting mitigation measures that should be more effective when the next big disaster occurs. Unfortunately, not always the mitigation strategies prove effective; the level of preparedness might not be enough for coping with disasters. Therefore, governments, at any level, are overwhelmed with response operations. Once response operations are considered "over," agencies start working on recovery. The emergency management framework consists of four specific phases: mitigation, preparedness, response, and recovery. During the mitigation phase, emergency managers, planners, and experts look at long-term solutions that aim to reduce the impact of hazards on infrastructures, lifelines, essential services, and communities; mitigation measures apply to the natural and the built environment. While mitigation aims to reduce the impact of hazards, preparedness instead focuses on how ready systems and communities are to respond to adverse events. Preparedness presumes an integrated set of activities that allow agencies and emergency services to be always efficient with sufficient resources, test of emergency procedures, and a continuous training through drills and large-scale simulations. The higher the level of preparedness, the higher is the efficiency of response. The response phase aims at deploying on the ground the available resources properly managed by emergency management agencies, emergency services, and other actors that normally work in the disaster relief field, in order to rescue citizens and animals and keep infrastructures functioning. The scale of a disaster is bidimensional: it contemplates a temporal dimension, which explains how prolonged the hazard and the impact can be. It may vary from hours to days. For example, heavy rains can be lengthy, generating widespread floods. Once the response phase is completed, and all the survivors are safely sheltered, lifelines and infrastructures are brought back to normal functioning; emergency managers typically evaluate damages and needs of the population. The system is now moving forward to the recovery phase. *Recovery* is the fourth phase of the emergency management framework. Unlike for the response phase, recovery does not have a predetermined time slot: some countries, by law, define how long a response can be or what goals can determine the response concluded. Although mitigation, preparedness, and response might be efficient and might have reached predetermined goals, some level of damage still persists. That level of damaged should therefore be removed, and the normalcy will be re-established.

Recovery is complex and highlights the necessity of an integrated approach, a decision-making process, and the participation of diverse stakeholders (Haddow et al. 2002). Federal or national, state, and local governments usually plan for each one of the four phases of the framework, in order to have a well-established plan of action, which sets priorities and steps when the situation requires.

The Federal Emergency Management Agency (FEMA 2016), which is the agency mandated of planning and responding at the federal level, has recently updated the National Disaster Recovery Framework (NDRF, 2nd edition). The document organizes processes and capabilities for effectively managing resources and establishing the best path to a successful recovery (FEMA 2016). The framework applies the concept of "whole community approach" in order to "restore, redevelop, and revitalize the health, social, economic, natural, and environmental fabric of the community." FEMA stresses the "whole community

approach" as a holistic approach, where citizens, businesses, nonprofit organizations, and all level of governments partner together to achieve successful results and outcomes.

Disaster Recovery: Theory and Research

Disaster recovery is commonly defined as a return to normal conditions after the occurrence of a disastrous event that disrupted the environment, the human life, and the social and the economic fabric. Some scholars have defined different stages of recovery. Quarantelli (1999) has found that there are different ways of naming this process, which might be different in particular aspects. The five terms identified through a rigorous bibliographic research are the following: (1) reconstruction, which focuses more on rebuilding infrastructures; (2) restoration, which presumes that a physical or social element is put back at the pre-impact stage; (3) rehabilitation, similar to reconstruction but focuses more on people than the built environment – in this case mental health is considered; (4) restitution, which seems to be more giving back something to the rightful owner through legal ways; and (5) recovery, which aims to find some level of acceptability after a disaster. Although research shows that different denominations exist, it is widely recognized that recovery is a process; this means that recovery takes place at distinct stages and presents different results and outcomes; and key elements play critical roles in achieving successful recovery. For its complexity, the recovery process impacts on the environment and human systems, the political sphere, the organizational capabilities, and the bureaucratic machine.

Recovery has also been explained through different theoretical frameworks. Throughout the recovery process, a multitude of elements or systems interact; some theories have been applied to understand the mechanisms that underlie the recovery process. Phillips (2015) presented an overview of the most widely accepted theories and applied them to the concept of recovery. *System theory* argues that the built, the human, and the natural environment are interconnected and dependent. After a disaster each one of the systems might be affected, resulting in impacts also on the other systems. Under systems theory, recovery would be effective if the dependencies and the interconnections disrupted are restored. *Vulnerability theory* focuses on those who are more at risk, claiming that within the society some individuals are more at risk than others. The recovery process, under this lens, should place emphasis in recognizing that vulnerabilities exist and are constituted by economic, gender, and race issues. The opportunity during the recovery process is to recognize these vulnerabilities and address them during the process, creating safer conditions for citizens.

As Phillips (2015) points out, disasters also impact on social interactions. The *sociopolitical-ecology theory* (Phillips 2015) explains how interactions within the human sphere influence the capability for humans to recover. The recovery process might witness a competition among groups to obtain more resources; there might be an imbalance of power, leading certain groups to have easy access to resources or impede others to obtain what they need. Under this theory, the recovery process should rebalance the power, reduce discrimination and corruption, and allow those affected to take part in the process.

When a disaster occurs, all the elements that constitute the society are affected. Within the society the bureaucratic machine can be affected. The *emergent norm theory* (Phillips 2015) considers the insufficient level of preparedness of the administrative structures for new types of events and the increasing number of organizations that step up on the stage to address the unmet needs that the ordinary administrative system is not capable of satisfying. This is the case of the numerous long-term recovery groups and emergent groups (Stallings and Quarantelli 1985) that appear after a disaster and work to achieve a successful recovery.

In post-disaster recovery, affected communities are not only hardly hit from a "damaged infrastructure standpoint"; they are predominately affected from a "sociocultural-economic standpoint." A very novel approach to explain how certain communities recover better than others,

and sometimes stronger than others, has been explained by understanding what makes a community well tied. The application of the concept of *social capital* as one of the many factors that facilitate recovery has shown that communities with high level of social capital can recover to normal life, better than others. *Social capital* has been defined in several ways, but in sum, it entails a set of norms, values, social structures, and social networks (Bourdieu 1986; Coleman 1988; Puttnam 2001) that citizens rely on in order to bond together and work together to solve problems; social capital exists when community members establish mutual trust, collaboration, and participation (Nakagawa et al. 2004). Some studies have shown how communities, having high social capital, have recovered to normalcy (Aldrich 2011; Nakagawa et al. 2004).

Key Operations in Disaster Recovery: Debris Removal, Shelter/Housing, Damage and Needs Assessment, Infrastructures, Financial Assistance

Disasters wreak havoc. Depending on the extent and the severity of the event, damage sometimes can be very substantial. After a disaster, local, state, and federal agencies coordinate to provide immediate assistance to citizens. As situation stabilizes, public officials are deployed on the ground to initiate a damage assessment that includes assessment of infrastructures and their level of damage and functionality (roads, lifelines, transportation, communication systems). Infrastructures, such as roads and bridges, are essential for accessing communities and delivering livelihoods and other materials. Without electricity, water, and gas, communities cannot perform daily activities: water is necessary for drinking and for personal hygiene. Electricity keeps communication systems up and running but is also necessary to families for cooking and heating. Once damage assessment is completed, public officials plan primary actions to speed the recovery of the damaged critical infrastructures and lifelines, by setting up contracts, generally with local private companies and contractors.

After a disaster, urban areas are inundated by a huge amount of debris. As Phillips (2015) points out, debris can be disaster-specific and require careful removal. Some debris might lead to dangerous ashes (asbestos) that threaten human life. Debris removal should be planned ahead, in order to identify specific areas that can collect debris. Some countries have issued specific regulation for managing debris after disasters. For example, the Italian Civil Protection Department (DPC) has issued a specific ordinance considering debris as special waste and delegating to regions the duty of managing debris removal and stock and, when possible, the recycling of materials, also contracting out to selected private companies. In addition, debris removal should comply with health and safety policies (Phillips 2015).

Sheltering and housing are critical actions that public managers must plan, if not ahead, right after a disaster. Sheltering operations have a variable span of time: it can vary from a week to more than a month; this is a rough estimate, because there are a range of circumstances that can impact on the time: time for moving to temporary houses, bureaucratic processes, and the geography of places. Sheltering should give the first point of relief for citizens that lost their own houses, providing comfort, food, clothing, special supplies, and emotional support. Sheltering is sometimes coordinated by emergency management agencies and large nonprofit organizations that deploy volunteers to open shelters in public schools, libraries, and other locations previously identified during the planning phase. Housing solutions come next; these can be described as temporary and permanent. Temporary housing provides families with a safe place to return to normalcy. Temporary housing presents various forms of lodging: rental units and mobile homes. Rental units can be houses or apartments. Families can autonomously find temporary solutions and apply for rental assistance. Rental units must accommodate needs and be affordable (Phillips 2015). Mobile homes are the second recovery solution for families and homeowners. Mobile homes are simple structures that can be easily moved where necessary. Mobile homes are not suitable for every place, since planners should identify safe areas

where these units can be allocated (Phillips 2015). Both rental housing and mobile homes, although suitable recovery solutions, sometimes present challenges for individuals: people with physical disabilities will find it hard to walk on stairs; or living in a mobile unit might not be suitable for everybody. In this perspective, recovery managers should identify needs and appropriately assign housing solutions to applicants.

In the immediate aftermath of an event, communities are severely impacted, and daily routines are disrupted. Families might lose their house; workers might quit their job because their business had to be shut down. There are specific needs that public officials and voluntary organizations must assess and evaluate and subsequently work to satisfy. Needs assessment is a systematic process to identify gaps between what is necessary and what is the actual condition. This process should take part immediately; generally, agencies perform needs assessment as the situation stabilizes. Key factors that must be considered in carrying out the assessment comprise full information about family status, health conditions, income conditions, immigration status, and language barriers that might impede families to apply for the proper assistance. During the recovery phase, agencies and nonprofit organizations set up an unmet needs committee, with the purpose of finding ways to help community members get the necessary means when they do not meet federal guidelines or do not have sufficient resources to get to ordinary life (Phillips 2015).

An essential aspect of every recovery process is the availability of financial resources and the identification of various streams of funding. Disbursing monetary resources requires careful planning, making sure that applicants will receive proper assistance. There is specific sequence of delivery that FEMA sets up right after a disaster; this sequence delineates all the steps that survivors should follow to get help. In the first place, voluntary agencies provide emergency relief items and food. Homeowners then apply for receiving financial assistance from insurance companies and the National Flood Insurance Program (NFIP). Then, citizens must apply for FEMA assistance that will provide economic resources for temporary lodging expenses, repair or replace assistance, and permanent or semipermanent construction. Besides FEMA's assistance, there are other state or agency supports that can provide economic means to citizens. One of these is the Small Business Administration (SBA) loans, through which applicants can get up to $200.000 for repairing properties. When citizens cannot cover all the expenses although they received the maximum allowed, FEMA can refer applicants to voluntary agencies, and unmet needs committees can determine the necessities and the amount of money they can provide.

Planning for Recovery

Emergency managers and planners in time of "peace" undertake a set of coordinated activities that establish tactics, strategies, and desired outcomes. The federal government and each single state emergency management agency have a branch mandated of planning and setting guidelines for disaster recovery. Disaster recovery plans lay out a well-established set of operations focusing on the state's capabilities of carrying out timely restoration, the backing up to normal operations of all the critical infrastructures (usually coordinated with private sector), the provision of housing, and the economic as well as social fabric of the affected communities.

FEMA's National Disaster Recovery Framework (NDRF) is a platform for the whole community that sets out the core principles and practices for building, sustaining, and coordinating the delivery of recovery capabilities (FEMA 2016).

FEMA's NDRF identifies the Recovery's mission as the functional area that will define the capabilities necessary for an affected community to rebuild the critical infrastructures, to provide immediate and adequate long-term housing, to provide livelihoods to sustain survivors' needs, to support health and well-being of the community, and to promote sustainable economic development.

Also, the NDRF emphasizes coordination among actors and identifies the major players that will carry out the recovery operations. The

Recovery Framework highlights eight core capabilities, and five are specific to recovery: (1) economic recovery, (2) health and social services, (3) housing, (4) infrastructure systems, and (5) natural and cultural resources. In addition, the NDRF emphasizes that local governments set up a local recovery office and state agencies provide adequate resources and necessary support to local governments.

A critical component of every recovery plan is the identification and the inclusion of the whole community, with its primary actors: individuals, families, homeowners, nonprofit organizations, and private sector. At the local level, municipalities have the primary responsibility of managing recovery efforts, with the support of state and federal agencies. Every plan must highlight the coordination structure: for example, in a state plan, the managing agency will identify the actors (NGOs, private, federal agencies) and how they will deliver assistance to local recovery agencies. Generally, states support local government when local resources are not enough or are exhausted or when resources are not available. The same goes with states that can request additional resources to the federal government or to other states through the Emergency Management Assistance Compact (EMAC). The state emergency management agency is responsible for managing state support operations and resources and, when in need, requests more resources to the federal government.

A good recovery plan should comply with the federal guidelines and be consistent with the Presidential Policy Directive 8 (PPD-8), Homeland Security Presidential 329 Directive 5 (HSPD-5), and National Incident Management System (NIMS). State and local planning must ensure that each one of the five core capabilities has a robust set of procedures that will ensure a timely start of recovery operations following the response phase. For every recovery function, FEMA and state agencies identify key agencies that are responsible for coordinating the delivery of resources, the implementation of planned procedures, the assessment of communities' needs, the evaluation of the recovery process, and the communication with partners and communities.

Economic recovery "is the ability to return economic and business activities (including agricultural) to a state of health and develop new economic opportunities that result in a sustainable and economically viable community" (FEMA 2016). State and local agencies will plan in order to identify critical economic sectors that sustain the communities and will identify and prioritize the distribution of available resources to the various stakeholders.

Infrastructures systems: the recovery function will ensure that critical infrastructure systems will be timely and efficiently restored and services will be provided to communities. In this regard, agencies must delineate a timeline according to which public and private sectors will operate and will ensure that lifelines and transportation systems are restored.

Health and social services: healthcare and social services are critical for an affected community. Without the proper functioning of social services, the well-being of a community is at risk. Planning the recovery of social services requires that agencies identify and assess primary needs and prioritize and coordinate actions with state and local service providers in order to restore social and health services and meet the need of the population.

Housing: housing is critical for a community during the recovery process. State and local agencies must plan for finding solutions that will support the needs of the whole community. As FEMA (2016) states, housing is critical and challenging: agencies must ensure adequate, affordable, and equitable housing solution and deliver all the available resources in order to provide housing solution to renters and homeowners. Housing function will identify temporary/transitional housing solution and subsequently long-term housing restoration.

Natural and cultural resources: the recovery function is also responsible for assessing the damage of natural and cultural resources. Natural environments and historical landmarks might be heavily damaged by disasters. Consequently, agencies must plan procedures that will support the preservation and restoration, through technical assistance, of areas and facilities damaged.

Recovery managers must identify available monetary resources that will support recovery capabilities in order to develop protection and recovery strategies.

Stakeholders and Actors in Recovery: Public, Private, and Nonprofit – Donation Management

FEMA's "whole community approach" emphasizes that all the parties involved in planning and responding to disasters have to work together to achieve greater and better outcomes. At every stage of the emergency management framework, public agencies and stakeholders share experience and knowledge to address the necessities that can arise in the pre- and post-disaster time. The recovery timeframe requires increased efforts to collectively meet communities' needs.

Actors that work together for a greater good comprise public agencies, the private sector, and the nonprofit sector.

Emergency management offices and other public agencies are in charge of operating recovery plans and managing projects. Also, they are responsible for financing operations and disbursing financial resources for homeowners, to repair and rebuild, and for businesses to restart their daily operations. If businesses need money, they can apply for Small Business Administration's (SBA) loans, at very low interest rates.

Public agencies can contract with private companies to restore critical services (power lines, etc.) or, as the case of New Jersey after Sandy, have contractors run the entire recovery programs. Unfortunately, NJ state received much critique when hired private contractors are paying out a colossal amount of money. However, private companies are critical in providing or tapping into specific services that cannot be otherwise provided by state or local agencies, for example, insurance companies and banks. Insurance companies, after the assessment of damage, pay out homeowners when they file a claim and banks can provide loans. One important service that the private sector keeps providing after disasters is transportation. Private companies can support transportation operations (daily transportation; moving goods) by contracting with public agencies.

The nonprofit sector is probability the biggest slice of the cake in terms of personnel and resources. Only in the USA, more than 1.8 million nonprofit organizations run daily services for communities. (Guidestar (2018): retrieved from https://www.guidestar.org/Home.aspx.) Many of these organizations have a disaster response/recovery mission. Among these, the Red Cross, the faith-based organizations, and the community-based groups respond to emergencies by running sheltering operations, providing food and livelihoods, assessing needs, and restoring and rebuilding houses.

After a disaster, there is an outpouring generosity. People donate goods and money to organizations; private foundations raise money for the nonprofits to be used for recovery projects. Donations management is sometimes burdensome and requires trained staff. Nonprofit organizations are held accountable for the money they spend and provide to citizens. During those times, material donations can be of obstacle. People tend to donate all the sort of goods sometimes not necessary research showed (Holguín-Veras et al. 2014), that material donations can complicate response efforts, news media and organizations are increasingly asking for money instead of material goods.

Integrating Mitigation into Recovery

As a community recovers from a disaster, emergency managers and city planners should consider strategies that integrate mitigation practices in order to reduce impacts of future events. Public officials should prepare a specific action plan that delineates what the future community would look like and ways they want to reduce as much as possible any likely damage. The mitigation plan's role is twofold: first, it serves as a document that encompasses a thorough risk analysis, including socioeconomic data of communities; second, it should be a regulatory document that will regulate any future project when it comes to rebuild or develop new areas.

After a disaster, there is a general concern for communities to rebuild as quickly as possible, avoiding lengthy processes and harsh public discussions that will likely hamper the ability to restore the original conditions. But sometimes building quickly is not the best strategy to adopt. There serious considerations that must be made based upon these questions: Do I rebuild? Do I relocate? And if so, where?

It is normal that survivors want to rebuild in the same place, because there is always a certain level of place attachment that keeps them in the same place. Or citizens recognize that rebuilding in the same area is not convenient and prefer to relocate. Relocating also raises the question whether move to a newly developed area or relocate in the closest urban area. Rebuilding in the same place should be done, only if the new project is compliant with the regulations that the mitigation plan imposes and according to strengthened building codes that the municipality should have designed in the new development plan. Survivors that relocate to a newly developed area should consider whether the new house is located in a low-risk area and all protective measures are adopted. Relocating in the urban areas can create some challenges. Word a part for relocating in the urban area. This solution is practical only if there are enough houses to be sold or rent; it is desirable if the urban area had little to no damage. And it is desirable because it can be less costly and economic development can benefit.

Since housing solutions are the main concern of emergency managers and city planners, a mitigation plan for future development should integrate how new lifelines will be built and made stronger to sustain impacts. For example, with high-speed winds and heavy rains, power lines can be severely damaged. The restoration of new power is costly, but adopting in-ground solutions (this happens in the majority of European countries) can reduce the likelihood that aerial power lines break down.

Public Participation in Disaster Recovery

Communities that are impacted by disasters are always encouraged to participate and design a recovery process. Engaging the whole community is central to the new approach to emergency management and especially to the FEMA's "whole community approach."

Public participation processes have been central to the large hazard mitigation planning literature, response and organizational behavior, collaborative processes, and less explored during disaster recovery processes. For example, Burby (2003) showed how collaborative and participative processes led to better planning procedures. Public participation is important for several aspects. First, citizens know the context of their communities and neighborhoods: they have knowledge of the social dimensions in which they live and all the critical factors that influence their communities (family status, poverty, etc.). The knowledge citizens have is an extremely valuable information for public officials when planning for recovery actions.

Second, participating in recovery and decision-making processes gives the right to citizens to express opinions and comments on projects. Depending on the level of participation, public officials can integrate proposed ideas for the establishment of priorities and delivery of resources, the satisfaction of primary needs, and the design of projects for restoring and developing the whole community. It must be clarified that every public participation process is composed of different factors: (1) a level of power held by the public official, (2) a level of power given to the community, and (3) consultation and negotiation practices.

Even if the public participation represents a high democratic value, integrating and designing participatory processes do not come always easily. First of all, public officials should understand what best participatory practice they can adopt. Participatory processes range from no or limited participation (citizens listen) to high involvement (citizens comment; express opinions; decide). Second, public officials must understand that a community presents a broad range of stakeholders, each one with different interests. Balancing all the interests presents a challenge that managers must confront. Third, public officials must choose the best participatory practice:

these include focus groups, advisory committees, forums, workshops, etc. Whatever the chosen techniques is, public officials should be able to keep a two-way and open communication with citizens at all times.

Public officials should be aware that failing in integrating public participation processes is easy. Regardless the techniques, public officials are required to communicate constantly with citizens and share important and useful information; otherwise the recovery process will not receive adequate public attention and support. Sharing information with the community is vital, and for this reason public officials should adopt the best strategy even when conditions do not allow, e.g., power outage.

In the recovery planning phase, public official should keep strong relationships with stakeholders, community leaders, and organizations, in order to collect critical information regarding their community, such as unemployment and poverty levels, minorities and underrepresented social groups, and people with disabilities.

Conclusion

Disaster recovery is mostly known as a concerted set of action aimed to restore pre-disaster conditions. Although this definition might not be quite exhaustive, research is still trying to define a theory of disaster recovery.

The post-disaster timeframe is characterized by extreme challenges, for which disaster recovery mangers have responsibilities to at least minimize. However, disaster recovery is a critical phase that can contribute to a new normalcy, when pre-disaster conditions cannot be restored.

After a disaster, recovery managers run operations that span across a broad range of sectors that include housing rebuilding, to business recovery, to critical infrastructures restoring. As all this operations are common during the recovery phase, planners and emergency managers should take advantage of normal situations and start planning for recovery. Planning is critical, because enhances public agencies' capability to effectively and efficiently run recovery operations, as well as, foresee necessary changes and measure to reduce impacts of future hazards as well as increase resilience of local communities.

Emergency Management: Shelter In-Place

Michael K. Lindell
Department of Urban Design and Planning, Institute for Hazards Mitigation Planning and Research, University of Washington, Seattle, WA, USA

Keywords
Structural resistance · Air infiltration · Air exchange · Dose reduction · Shelter in-refuge

Definition

Shelter in-place consists of remaining in a location, usually a structure, that provides greater protection against an environmental hazard than being outdoors. Shelter in-place is appropriate for situations when the shelter location provides adequate protection against hazard exposure but also might be chosen when insufficient time for evacuation would lead to being exposed to the hazard in a vehicle that provides even less protection than the shelter location.

Introduction

The essential distinction between shelter in-place and evacuation is that the former generally provides protection by shielding from a hazard, whereas the latter provides protection by distance from the hazard. There is a variation on shelter in-place, shelter in-refuge, that can be used when there are nearby locations that are safer than the locations where people find themselves when they recognize the need to take protective action. For example, a coastal community at the tip of a peninsula might have a tsunami vertical evacuation shelter that can be reached much more rapidly than evacuating to high ground at the base of that peninsula.

There are three major mechanisms by which sheltering in-place provides structural resistance against environmental hazards such as tornadoes, hurricane wind, wildfires, inland floods, storm surges, tsunamis, earthquakes, volcanic eruptions, and hazardous materials releases. First, a shelter can provide protection against the extreme pressure of wind and water hazards or against the extreme temperature of wildfires. Second, a shelter can provide protection from inhalation of hazardous materials such as toxic chemicals or volcanic ash. Third, a shelter can provide protection from direct radiation produced by an overhead plume or ground deposition of radiological materials.

Protection from Extreme Pressure or Temperature

Regarding the first mechanism, protection from wind and water pressure or from fire temperature, structures can lack resistance to environmental hazards because of inadequate designs, inadequate construction materials, or both (AIA 1995; IBHS 2007). In high wind (including tornadoes and hurricanes) and explosions (usually technological in origin, but also including some volcanic eruptions), a substantial increase in air pressure can cause structures to collapse. *Fortified* homes (https://disastersafety.org/fortified/) have connections and braces that reinforce roofs and gable-end walls against wind attack. In addition to positive pressure on upwind walls, high wind creates negative pressure, or suction, as it is forced to flow up and over the roof. This suction is greatest in flat roofs, intermediate in gable-end roofs (which slope in two directions), and least in hipped roofs (which slope in four directions). Suction tends to lift the roof from the walls unless resisted by adequate connections to the walls – which in turn, must have adequate connections to the foundation. Adequate designs and materials also provide protection to building openings such as windows and doors, thus preventing the wind from pressurizing the interior and adding to the stress on roof and walls. There is a need for window and sliding glass door shutters to resist the direct pressure of the wind and the impact of flying debris. However, door reinforcement is also important – especially for double-wide (two car) garage doors that are highly susceptible to failure

because their great width allows the wind to deflect them inward and pull the rollers out of their tracks.

Both riverine flooding and hurricane storm surge require the structure to have foundations anchored deep enough to resist scouring by water currents that can undermine building foundations and cause structural collapse. In addition, structures on the open coast must be of sufficiently sturdy construction that they can resist the direct impact of storm surf and battering debris from structures that have already been destroyed. Additional protection can be provided by floodproofing that uses waterproof construction materials, sealing of cracks, provision of valves on sewer lines, steel bulkheads for lower-level openings, and sump pumps to eject seepage. Tsunami impact poses an even greater threat than inland flooding or storm surge. These sea waves can threaten areas as much as 100 feet (30 m) above sea level, so destruction is highly likely for most structures located very near the shoreline. However, properly designed steel-reinforced concrete structures located a short distance inland are likely to resist even the largest tsunamis.

Wildfire hazard requires fire-resistant structures whose exterior walls are constructed of nonflammable materials such as metal, concrete, or masonry, and whose and roofs are metal or tile (see NFPA 2018). In addition, wooden doors should be replaced with metal ones, tempered glass should be installed to protect windows, and vents should be covered by metal screens. Such structures should be surrounded by a *defensible space* that is created by clearing vegetation from a 30 foot (9 m) perimeter around any structure, choosing fire-resistant plant varieties, and maintaining landscapes to reduce the buildup of flammable materials such as dead leaves and fallen branches (IBHS 2007).

Protection from Inhalation Exposure

The principal sources of inhalation hazards are airborne toxic and radiological materials (USEPA 1987). An enclosed space will resist infiltration if it can be closed tightly enough to keep out the hazardous material and has enough oxygen to sustain those within it until the danger has passed. Unfortunately, most structures are leaky, allowing contaminated air to infiltrate even when the doors and windows are closed. The rate of air exchange increases with the amount of leakage area, the wind speed, and the temperature differential between the indoor and outdoor air (Sorensen et al. 2004).

The rate at which indoor and outdoor air are exchanged is commonly measured in air changes per hour (ACH). However, emergency managers will find it more useful to think of air exchange in terms of turnover time, which is the reciprocal of the air exchange rate, or $t_B = 1/ACH$, where ACH is the number of air changes per hour (Mannan and Kilpatrick 2000). As Wilson (1987) emphasizes, an infiltration rate of 1.0 ACH does not imply that all the clean air will be gone in 1 h. Rather, the proportion of contaminated air gradually rises until 63% of the original air has been replaced by contaminated air at the end of 1.0 t_B hours and 95% of the original air has been replaced by the end of 3.0 t_B hours. Thus, for the case of 1.0 ACH, it will take over 3 h (not just 1 h) for the indoor air to become almost completely contaminated. This result is extremely important because it indicates that in-place sheltering is more effective than most people might infer from the apparent implication of the number of air changes per hour. The reason for the difference between the apparent result and the correct result can best be illustrated by examining the difference between the apparent, but incorrect, mechanism of air exchange and the actual mechanism. It would only take 1 h to replace the clean air (the incorrect result) if the contaminated air somehow "pushed out" the clean air, but this is not what happens. Rather, the contaminated air that infiltrates the structure mixes with the clean air rather than "pushing it out." Clearly, exfiltration of a mixture of clean air and contaminated air will take longer to exhaust the clean air in a structure than will exfiltration of ("pushing out") clean air alone. Consequently, sheltering in-place is at least three times as effective in reducing inhalation exposure as it might appear to be.

Although this time lag effect is important, it is not the only mechanism by which sheltering

in-place can reduce adverse health effects; there is also a damping effect that reduces the peaks in plume concentrations. The fluctuations in wind speed and direction that produce these peaks arise from irregularities in meteorological conditions and local terrain. One way of measuring peak concentration is by estimating the value that is exceeded approximately 1% of the time. Wilson (1987) reports that in the outdoor (contaminated) air, such 1% peak concentrations are 400% as large as the mean concentration. For indoor air, the equivalent peak concentration is only 50% larger than the mean. This is, of course, of considerable significance when peak concentrations are the principal health threats.

As Wilson (1987, 1989) and others have observed, a major problem in assessing the effectiveness of shelter in-place is uncertainty about whether indoor air concentrations will remain sufficiently low for a sufficiently long period of time. This can be answered definitively only if there is information about the hazardous material being released (especially the identity of the material released, and the rate and duration of the release), local weather conditions (wind speed, wind direction, and atmospheric stability), and the air exchange rates for the structures in the hazard impact area. Data on the release and the meteorological conditions are not available until an incident occurs, but data on air exchange rates can be collected in advance. First, Rogers et al. (1990) report that energy conservation research has shown air exchange rates in most US dwellings range from 0.5 to 1.5 ACH. Second, Wilson (1989) reports that the most important factor affecting a structure's air exchange rate is its leakage area, which is substantially determined by the presence of a vapor barrier in the walls and ceiling of a structure. This is a feature that is most common in houses built in cold climates after 1960. Thus, emergency managers can estimate the effectiveness of sheltering in-place in their communities by obtaining local utilities' data on the age of the housing stock within different neighborhoods, focusing especially on neighborhoods with older, smaller homes occupied by low-income households (Chan et al. 2007a, b). Special facilities, especially those such as hospitals that have low mobility residents, should be examined individually to assess their air exchange rates.

Protection from External Radiation Exposure

In addition to being an inhalation hazard, a plume of radioactive material can cause harm by means of external gamma radiation from the cloud and from ground contamination. Dense building materials such as concrete, brick, and stone provide shielding from external gamma radiation and, thus, can provide a basis for sheltering in-place during radiological emergencies. The effectiveness of structures made from different types of building materials has been examined in number of research studies (see Lindell et al. 2006, for a summary). These studies calculated the dose reduction factors (the ratio of the dose received while sheltering to the unprotected dose) for three exposure routes: external gamma radiation from the cloud, external gamma radiation from ground contamination, and inhalation of radioactive materials infiltrating into the structure. Burson and Profio (1977) found that sheltering in a wood frame dwelling provides little more protection from cloud and ground exposure than does "sheltering" in a vehicle while evacuating. Sheltering on the ground floor of a masonry home with no basement or in the basement of a wood frame home gave considerably higher levels of protection: about 50% of the unprotected exposure to the cloud and less than 20% of the unprotected exposure to the ground. As one might expect, the basement of a masonry house was even more effective: 40% of the cloud exposure and 5% of the ground exposure. A large office building was the most effective shelter of all, reducing cloud exposure to about 20% and ground exposure to 1%.

McKenna (2000) reported the results of an extensive series of analyses by the Nuclear Regulatory Commission, which examined the relative effectiveness of continuing normal activity, sheltering in a home basement or large building, or evacuating before or after plume arrival at three distances from the plant. These analyses confirmed the results of earlier studies by finding that even a late evacuation is better than home shelter, large

building shelter is better than late evacuation, and early evacuation is best of all. Thus, those who are within 5 miles of a nuclear power plant have high vulnerability if they remain in their homes during a release. Only large building shelter provides as much safety as early evacuation.

Implementing Shelter In-Place

The steps required to implement shelter in-place vary somewhat by hazard. There is usually no forewarning for earthquakes, so people can typically protect themselves only by sheltering beneath a sturdy piece of furniture ("duck, cover, and hold on") in the room where they are located when the shaking begins. There is usually more forewarning for tornadoes, so they can shelter in the basement or, if none is available, in an interior room. With forewarning of a hurricane, people can install shutters on windows and brace doors before hurricane wind becomes too strong. For a flood, they can fill and place sandbags before proceeding to an upper floor. For a wildfire, people can clear a defensible space before retreating inside. Finally, for toxic chemical releases, shelter in-place involves going indoors; closing doors and windows; turning off heating, ventilation, and air conditioning systems; and, if possible, taping the cracks around doors and windows – which takes approximately 17 min for a single room (Rogers et al. 1990). However, in chemical emergencies, it is also important for people to tune to the emergency alert system so they can receive further instructions about when to open doors and windows after the plume has passed (Sorensen et al. 2004). Airing out the structure immediately after plume passage is important because, at that point, the inside air is more contaminated than the outside air.

It is important to recognize that, in some hazards, people's decisions to shelter in-place are affected by their desire to protect property from hazard impact (Cova et al. 2009). For wildfire protective action decisions, the number of people who take this "stay and defend" option is a significant percentage of those at risk (McCaffrey et al. 2018). For other hazards, such as toxic chemical releases, property protection is not possible, so the decision to shelter in-place depends almost exclusively on people's perceptions of its efficacy in protecting people. In this case, a shelter in-place recommendation is likely to elicit low compliance (Sorensen et al. 2004), but compliance might be improved if authorities explain why shelter in-place provides effective protection and why evacuation might result in "sheltering" in a car when overtaken by a chemical plume.

Conclusions

Shelter in-place can be an effective method of protecting people from a variety of different environmental hazards. However, its suitability depends on the characteristics of the hazard, local weather conditions, and local building stock (including the variability in the shelter suitability among structures within the community). In addition, risk area residents' motivation to shelter in-place depends on their perceptions of its effectiveness in protecting persons and the degree to which it allows them to protect their property as well. Emergency managers need to thoroughly examine the feasibility of this protective action before an emergency occurs to ensure that a recommendation to shelter in-place will achieve a high level of compliance and will effectively protect the population at risk. It is especially important to develop procedures that identify in advance "who should be warned to do what and when" (Cova et al. 2017).

Emergency Management: Spontaneous Volunteers in Response to Disaster

Lisa C. Orloff
Worldcares, New York, NY, USA

Keywords

Spontaneous volunteers · Disaster response · Disaster volunteerism · Community response · Convergence · Volunteer reception centers

Definition

Spontaneous unaffiliated community volunteers (SUCV) or just-in-time volunteers are defined as "citizens with knowledge of the area and ties to the community; they may or may not have training or experience in emergency response, but most possess skills from their everyday life experiences, job experiences, or experiences due to their responsibilities in running a household, managing volunteer responsibilities etc." (Orloff 2011, p. 83).

Introduction

Spontaneous volunteerism is a part of the history of disaster response (Katz 1989; Points of Light Foundation 2002). As long as there have been disasters, individuals and communities have emerged to help their neighbors and fellow human beings. For example, during the 1859 Battle of Solferino, Henri Dunant's spontaneous volunteer efforts led to the founding of the International Committee of the Red Cross. The human need to connect to others and help others in need is innate and has been demonstrated in a variety of disasters, such as the 1917 Halifax ammunition ship explosion, the September 11th attacks, Hurricane Katrina, and the 2011 Tōhoku earthquake and tsunami (Points of Light Foundation 2002).

Despite the natural inclination of human beings to respond to crisis, between 1978, when FEMA was established through the 2005 Hurricane Katrina response, spontaneous community volunteerism was considered a challenge and a hindrance by official disaster managers (Orloff 2011; Points of Light Foundation 2002, 2005). People coming out of their homes and places of work to help was often referred to as "a disaster with in a disaster" because these individuals and groups sometimes created management challenges for official responders. "When disaster strikes, emergency management and voluntary agencies automatically mobilize. Each has a specific role to help ensure a community's successful response to and recovery from the disaster's devastation" (Points of Light 2002, p.). These groups are trying to focus on helping the community with their own experienced workers but are now burdened with the task of simultaneously overseeing these spontaneous, unaffiliated volunteers (Points of Light Foundation 2002, 2005). This may mean using some of their staff to work with the volunteers rather than directly helping the victims.

In 2011, the perspective regarding who should and should not be involved in disaster response shifted. With an increase in frequency and impact of disasters, FEMA administrator, Craig Fugate, acknowledged the limits of the government in meeting the challenges posed by a catastrophic incident and accepted societal volunteerism (FEMA 2011). Subsequently, guides and playbooks and new approaches have been published to help individuals, communities, organizations, and government work together to achieve a whole of community approach to disaster response. This chapter will provide information regarding the various management methods in place to help agencies deal with spontaneous volunteers during disaster and provide concrete guidelines from the volunteer reception center (VRC) method that was implemented in 2011.

Management Methods

The most effective way to integrate spontaneous volunteers into the disaster response is by leveraging preexisting and proven management systems, including the National Incident Management System (NIMS), the Incident Command System (ICS), and the methodologies within them (Points of Light Foundation 2002). FEMA (2017) released a revised NIMS doctrine that provided "a common, nationwide approach to enable the whole community to work together to manage all threats and hazards" (para 1). NIMS applies to all incidents, from traffic accidents to major disasters, regardless of cause, size, location, or complexity (Haddow et al. 2017).

According to FEMA (2017):

> NIMS guides all levels of government, nongovernmental organizations (NGO), and the private sector to work together to prevent, protect against, mitigate, respond to, and recover from incidents. NIMS provides stakeholders across the whole community with the shared vocabulary, systems, and processes to successfully deliver the capabilities described in the National Preparedness System. NIMS defines operational systems, including the Incident Command System (ICS), Emergency Operations Center (EOC) structures, and Multiagency Coordination Groups (MAC Groups) that guide how personnel work together during incidents, from traffic accidents to major disasters. (para 5)

The ICS is a fundamental element of incident management under which command for disaster management, particularly, emergency preparedness and management, is centralized and

controlled through the EOC. The EOC allows the community businesses to continue functioning during the disaster. Coordination and support for disaster management comes from the MAC groups which combine people, processes, communication, equipment, and facilities into a common system.

The organization and terminology used by ICS facilitate its effectiveness (FEMA 2017). The structure of ICS corresponds with command, operations, planning, logistics, intelligence and investigations, finance, and administration functional areas as a means of enabling various groups to perform their tasks (FEMA 2017). By standardizing the management process, ICS allows the incident managers to determine which elements of the incident must be performed quickly. There are a variety of tasks that must be performed, including designating oversight of the incident; dictating which group reports to which agency; determining the optimal span of control (i.e., number of subordinates managed by a supervisor); and meeting twice daily with teams for briefings and debriefings. All of these crucial tasks culminate into a management system that can be applied to spontaneous volunteer and successfully applied to the management of the volunteer reception center as explained in the next section.

The Volunteer Reception Center (VRC) Model

According to Orloff (2011), the volunteer reception center (VCR) model provided both structure and planning for how to oversee spontaneous volunteerism during disasters. Table 1 presents the five different types of volunteers that are typically available during disasters. Each type offers a different set of skills and ties to the community and thus requires varying levels of supervision. There are fundamental elements of spontaneous volunteer management that are quite simple in philosophy but a bit more complicated to coordinate in reality. If an agency is seeking to manage spontaneous volunteers within an unfamiliar community, it is important to engage a trusted, local leader to act as a liaison. This individual will have the trust of the community and provide validation for the group wishing to organize the community.

Emergency Management: Spontaneous Volunteers in Response to Disaster, Table 1 Types of volunteers and their skills and community ties (Orloff 2011)

Type of volunteer	Description of skills and community ties
Agency-affiliated pre-trained volunteers	Volunteers are registered with your agency prior to disasters and have been through your agency's standards of background check, training, and credentialing as well as gained a history of volunteer service with your agency
Registered volunteers	Volunteers are registered through application, but may not have taken any of your agency's training or gained a history of volunteer service with you
Partnering agency-affiliated pre-trained volunteers	These volunteers have been trained by groups that you know in your community, such as faith-based organizations, the boy scouts, Lions Clubs, CERT teams, and PTA members. Affiliated volunteers with disaster management training may include those who volunteer for groups like The Salvation Army, United Way, Habitat for Humanity, and Doctors Without Borders
Spontaneous unaffiliated community groups	Many nonprofit groups do not have a disaster-related mission, but will find themselves and their constituency emerging to help in some way in the event of a disaster. Such groups may include faith-based groups, the national reserves, professional and trade-person associations, and clubs, such as rotary, Lions Clubs, and boy scouts, as well as businesses within your community, like Walmart or World Central Kitchen
Spontaneous unaffiliated community volunteers	Citizen in your community who have ties and knowledge of the area. They may or may not have training or experience in emergency response. Most volunteers do, however, possess skills from their everyday life experience, job experience, or experience due to their responsibilities in running a household, managing volunteer responsibilities, etc.

The VRC model "outlines the steps for the set-up of a room or building that will put a roof, both literally and functionally, over the Spontaneous Volunteer management process. . .including spot screening, selection, and placement of spontaneous volunteers This model can help to address the internal capacity challenges that emergency managers face, especially by drawing volunteers as additional capacity and resources to one central location to implement much of your volunteer management protocols and process" (Orloff 2011, p. 125). While there are several floor plans for a VRC, it is the management structure that is most important (Orloff 2011; Points of Light Foundation 2005). Once volunteers are engaged, either by spontaneously showing up or because an agency has solicited them, they must first be registered using either a registration form or a volunteer application. Next, volunteers should be interviewed in order to understand what skills they possess and how best these skills should be used. They will be matched to a specific role, such as ditch digger or which may require a short training session. If the VRC is deploying teams such as in a muck and gut operation post flooding, the volunteer is then paired with a team that follows the incident command structure that will include a team leader, a safety officer, and up to seven workers. The volunteer is then given personal protective equipment and other tools for the assigned role and a volunteer work order. The volunteer is then part of a team and would deploy into the field to conduct daily activity and return to the VRC to debrief and decontaminate.

Alternatively, a VRC will act as a coordination and referral center to match volunteers to agencies in need of volunteers rather than deploying teams directly into the field. In this case, the agency may have a desk in the VRC, or a person may screen and refer the volunteer to go to the agency where the agency processes are undertaken (Orloff 2011; Points of Light Foundation 2005). Voluntary agencies active in disasters can set up the VCR and also coordinate with their network partners through daily calls and reports into an operation center, where an individual representing voluntary agencies active in disaster has a seat. Timing is important as well given that when disasters occur, systems will not be in place or available, leaving a lag time. If there is urgency in needs or few resources available due to the disaster, various elements in the VRC, such as background checks of volunteers, may be skipped (Orloff 2011).

Building Resilience

The impact of disasters often leaves survivors with a sense of disempowerment. "After a disaster, the number of people with psychological trauma exceeds the number of people with physical injury by as much as 40 to 1' (Links 2017, p. 1). In particular, many people in the community have suffered loss of life and/or property and as a result them feel little control over the situation or their lives. Hence, spontaneous volunteerism is an instinctual way for people to regain control after a disaster and to build resilience during recovery (Steffen and Fothergill 2009). Active involvement in their own community allows these survivors to reposition themselves as volunteers and reconnect with other residents in a positive, prosocial and therapeutic manner that lasted post-disaster. According to Steffen and Fothergill (2009): "taking action facilitated meaningful therapeutic recovery from feelings of victimization following the event. In addition to the apparent long-term impact on personal healing, the opportunity to volunteer had lasting impacts on self-concept that translated to significant changes in life choices" (p. 29). Thus, volunteerism strengthened community relationships, which would be essential in neighborhoods where disasters commonly occurred (Links 2017).

Conclusion

According to The Borgen Project (2015), the average number of natural disasters, especially related to climate, has increased from 1970 to 2009, impacting millions of people worldwide. It is not sufficient to rely only on government resources when dealing with disasters, as shown by many of the catastrophes that occurred nationwide over the past 40 years (FEMA 2011) recognized that a government-centric approach to disaster

management was insufficient to meet the challenges posed by most catastrophic incidents occurring in the United States. Consequently, FEMA (2017) revised existing systems, including NIMS, ICS, and the VRC, in order for them to be available for adaptation in any circumstance. The VCR model, in particular, helped various agencies to supervise spontaneous volunteers in communities where disaster occurred and ensure that systems for preparation were in place beforehand, during, and post disaster that protected them from harm and supported community recovery.

Emergency Management: Working with Vulnerable Populations

Health and Human Services Department, SUNY Empire State College, Selden, NY, USA

Keywords

Aging · Disability · Immigrants · Refugees · Socioeconomic · Vulnerable populations

Definition

Emergency management situations often require that workers render aid to populations who have disabilities or are vulnerable. For purposes of this chapter, a person with a disability can be defined as someone who may function on a daily basis with little assistance to someone who may have

difficulty in performing functional tasks or daily living activities and generally meets the federal definition. The federal definition includes people with physical/functional disabilities as well as cognitive and emotional such as a learning or developmental disability and mental illness. People are considered to have a severe disability if they are unable to perform one or more of these tasks or activities, need personal assistance, or have one of the severe conditions described in the report. Vulnerable populations refer to people who have increased risk of disruption or death during and after a disaster including people living in poverty, immigrants and refugees, women and girls, and people with disabilities and the aging.

Introduction

This chapter discusses the disability and vulnerable populations in terms of how emergency managers, field personnel, and first responders interact with and support them during disasters and crises. Notably, this group requires greater assistance during emergency situations mainly because they lack access to a variety of things that most people take for granted, such as healthcare, employment, and school, and they have higher rates of poverty and suffer worse socioeconomic outcomes than those without disabilities (World Report on Disability 2011, p. xxi). These intersecting factors present an opportunity for emergency managers, field personnel, and disaster human service agencies to work with, support, and include and integrate people with disabilities and vulnerable populations into all phases of emergency management (mitigation, planning, response, and recovery). However, it is paramount that the emergency management field understands basic parameters and context in which people with disabilities and vulnerable populations live on a daily basis in order to better assist them when it is most critical. In particular, there are many individuals living independently with a disability or coexisting disabilities. In addition, there is a difference between people who have a disability and those who have a medical condition; it is important to keep in mind that because a person may have a medical condition, it does not mean she or he has a disability, though it could.

Understanding differences between "legally protected class" and identifying people with specific needs impacts the type of post-disaster services they may or may not be guaranteed. As per the Americans with Disabilities Act (ADA), persons with disabilities are a legally protected class (Older people are also a protected class under the Older Americans Act.) and can use the ADA as statutory authority for enforcement and lawsuits. An individual is someone with a disability if the following is true: he or she (1) has a physical or mental impairment that substantially limits a major life activity; (2) has a record of such an impairment, and/or; and (3) is regarded as having such an impairment (A Guide to Disability Rights Law 2009). According to ADA, the type of disabilities (including the age spectrum from pediatric to geriatric) are: (1) physical (e.g., severe arthritis, spinal cord injuries, people who use wheelchairs, people with multiple sclerosis); (2) sensory (e.g., people who are blind, deaf, hard of hearing); and (3) cognitive (e.g., people with mental illness, learning disabilities, mental retardation/developmental disabilities) (A Guide to Disability Rights Law 2009). In addition, to a person identifying as having a disability, it is equally important to recognize that some people are living with two or more disabilities. For example, there may be a person who is deaf and has a learning disability, who has cerebral palsy and general anxiety disorder, etc. The purpose of this chapter is to provide first responders with information on how to develop emergency management plans that will benefit disability and vulnerable populations in a crisis.

Disability and Vulnerable Populations

The ADA of 1990 does not specifically address the issue of compliance in emergency planning and response. However, it does mandate that all public and private sector facilities come into and remain in compliance, provide reasonable accommodations, and be accessible (Davis and Sutherland 2005). Per federal law, shelters and

other disaster-related services must be accessible to people with disabilities (FEMA 2010). In recent years, FEMA has provided clear written guidance on this including in shelters (FEMA 2010). Access must be both physical (e.g., architectural barriers) and programmatic. FEMA clarifies those with functional needs as:

> Functional Needs Support Services (FNSS) are defined as services that enable individuals to maintain their independence in a general population shelter. FNSS includes:
>
> - reasonable modification to policies, practices, and procedures
> - durable medical equipment (DME)
> - consumable medical supplies (CMS)
> - personal assistance services (PAS)
> - other goods and services as needed. (FEMA, Guidance on Planning for Integration of Functional Needs Support Services in General Population Shelters 2010, p. 8)

Populations who have special needs, including disabilities, comprise vulnerable populations, but are not protected legally in the way that ADA protect people with disabilities (Kailes and Enders 2006). According to the EAD Toolkit (2007), these groups include (list adapted from EAD Toolkit 2007): (1) Refugees and immigrants including documented and undocumented people; (2) non-English speaking/English proficiency including those whom English is not their first language as well as individuals who have low English comprehension/literacy issues either because of or not because of a cognitive disability; (3) homelessness and disability issues, specifically mental illness and physical disabilities; (4) low income; and (5) residential care facilities that may include nursing homes, assisted living centers, drug treatment centers, group homes, residential homes, foster homes, adult and childcare facilities, etc. Health and Human Services (HHS 2006) specified that anyone who may be at risk because of their age, status, or physical condition would be considered to have special needs during public health emergencies.

The broad nature of the usage of the term "special needs" or vulnerable populations can lead to confusion during and after a disaster. During the 2007 California wildfires, confusion regarding the term special needs hindered the response. According to the After Action Report authored by Kailes (2008), "The term 'special needs' does not work because it does not provide guidance to operationalize needed planning tasks. A better way to think about the needs of people with disabilities and activity limitations is to use a function based orientation that considers major functional needs: communication, medical, maintaining functional independence, supervision, and transportation" (p. 33).

Age

First responders should note that a person's age, whether juveniles (not yet 18) or adults beyond middle age, is linked to vulnerable populations and disabilities. Prior to adulthood, children and adolescents do not have the cognitive capacity to deal with emergency situations and very young children (infants through preschool age) have limited physical capacity as well.

Similarly, older people are likely to have physical and/or cognitive disability. The US Census (2017) indicated that there were 47 million Americans aged 65 and older, with approximately 75% claiming to have one or more disabilities. The number of people over 60 with disabilities is expected to grow as the Baby Boomer generation (born 1940 through mid-1960s) ages. The location in the United States of residents may also be relevant, particularly as there are large aging population living in retirement communities in the South (40%), with New Orleans alone reporting 23% of adults with a disability (Kraus et al. 2018, p. 8).

The disproportionate impact of disasters on people with disabilities and seniors is heavily documented as recently evidenced after Hurricane Katrina hit the Gulf Coast in 2005 and from past disasters such as Hurricane Andrew in 1992 and the major hurricanes of 2004 that impacted Florida. Of the estimated 1,800 persons who died in Hurricane Katrina and its aftermath, 71% of the victims were older than 60, and 47% over the age of 75. Of the elderly affected by Katrina, most lived independently, and many were disabled and mobility-restricted (Cahalan and Renne 2007; Davis et al. 2009). Supporting this finding, of the 144 total deaths caused by the four major

hurricanes that hit Florida in 2004, 40–60% were persons over the age of 60 (Cahalan and Renne 2007). Studies have attributed increased vulnerabilities (disabled and seniors) to disasters primarily to impaired physical mobility, diminished sensory awareness, preexisting health conditions, and social and economic constraints. According to Phillips, "Higher injury and death rates occur because seniors are less likely to hear warnings, are less able to evacuate effectively or are reluctant to leave their homes, or because they live alone and have few sources of support for evacuation" (Phillips and Morrow 2007, p. 1). She further states, "During response and recovery, the elderly is less likely to use federal programs because they find the rules and regulations of federal bureaucracy to be confusing and a burden" (Phillips and Morrow 2007, p. 1).

Poor planning with and for the disability and aging population also contributes to increased vulnerability during a disaster response and recovery phase. This lack of comprehensive planning further leaves people with disabilities at risk and with fewer options.

Persons with Medical Conditions

Many people throughout the United States may have one or more existing medical conditions, some more severe than others. (If a person with a medical condition becomes debilitated, limited, or otherwise impaired, that person with the medical condition may be protected under the ADA.) Some medical conditions are also defined as a disability and therefore those persons are considered a protected class. For example, people with psychiatric disabilities are included in the ADA definition of "cognitive disability" and are protected under the ADA. However, a person who is deaf may or may not identify him/herself as someone who has a "medical condition," but they are still protected under the ADA.

Examples of medical conditions include people with cancer, Alzheimer's, kidney disease, multiple sclerosis, diabetes, HIV/AIDS, etc. Caring for people with medical conditions is critical during the recovery period and often an aspect overlooked. If medical infrastructure is not maximally functioning during the recovery process, some people with medical conditions may either suffer or not be able to return home. For example, if an evacuee depends on dialysis treatment several times a week and the dialysis center is not functional after the disaster, more than likely that person will either have to stay in an alternate care facility or not able to return to home. This can be particularly disconcerting for people are socially and medically dependent on neighborhood services as well as living independently.

Socioeconomic Status and Ethnicity

People with disabilities are more likely to live at or below the poverty level and have limited access to resources. People with disabilities are nearly twice as likely as people without disabilities to have an annual household income of $15,000 or less (Davis 2005). Most live at a "disadvantage" prior to a disaster, making the effects of the disaster devastating. According to the World Bank, "Poverty causes disabilities and can furthermore lead to secondary disabilities for those individuals who are already disabled, as a result of the poor living conditions, health endangering employment, malnutrition, poor access to health care and education opportunities etc. Together, poverty and disability create a vicious circle" (World Bank Poverty and Disability n.d., main web page).

As poverty rates more generally continue to rise in the United States with 58 million workers making less than $15 an hour and considered "working poor," this impacts not only how the emergency management community responds to and supports recovery but is specifically related to people with disabilities. The unfortunate reality is that several people with disabilities are also located in lower economic brackets. There are approximately 53 million people with one or more disabilities living in the United States (Centers for Disease Control 2015). Unemployment rates are higher among people with disabilities with over 65% of working-age adults with disabilities unemployed. Of these working adults, nearly one third earn an income below the poverty level (Fessler 2015; Fontenot et al. 2018). According to the National Council on Disability (NCD),

> [T]he employment rate of working-age people with disabilities remains only half that of people without disabilities (38 percent compared with 78 percent in 2005). The reason is not that people with disabilities do not want to work: Two-thirds of non-employed people with disabilities say they would prefer to be working. (National Council on Disability 2007, p. 8)

People with disabilities who cannot work full time must depend on Social Security Disability Insurance and Supplemental Security Income to support them. Generally, federal benefits are inadequate and do not "provide a living wage, making poverty an inevitability" (Atkins and Guisti 2003, p. 1). As barriers are broken down and disability rights advocated, people with disabilities are living more independent lives and becoming more integrated into communities and workplaces. Almost half of people with a disability (an estimated 24.1 million people) are considered to have a severe disability. For more than a third of individuals with disabilities, assistive technology is essential to being able to take care of themselves at home (Davis 2005). According to Stapleton et al., "Working-age Americans with disabilities are much more likely to live in poverty than other Americans and generally did not share in the economic prosperity of the late 1990s. At the same time, public expenditures to support them are growing at a rate that will be difficult to sustain when the baby boom generation retires and begins to draw Social Security Retirement and Medicare benefits" (Stapleton et al. 2005, p. 1). Still, economic concerns remain as people with disabilities continue to be a marginalized group.

The term "vulnerability" is often used within different contexts. Planners and geographers will look at geographic vulnerability, such as coastal areas and how hurricanes may affect them (Fordham et al. 2013). In addition to geographic, or location-based, vulnerabilities, there are social vulnerabilities. According to Fordham et al. (2013), social vulnerability "arises out of differential social relations among groups in a given society" (p. 4). For example, social vulnerability includes issues such as income disparity, disability, access to health and mental health, cultural and language differences/diversity, race/ethnicity, and gender (Fordham et al. 2013). Along these lines, in this chapter, we will look at "social vulnerabilities" as it is applied to "vulnerable populations." Vulnerable populations may include individuals and communities that experience barriers to services during and after a disaster or major crises. These populations include people living in poverty and working poor, people with disabilities, older people, and refugees and immigrants. Certain ethnic groups have high rates of disability, including African-Americans and Native Americans at 24.3%, as compared to Asian Americans who have the lowest at 16.6% (Fontenot et al. 2018).

It is important that local emergency managers identify the vulnerable populations within their community and engage with them in planning, response, and recovery processes. People who are vulnerable before the disaster or major crisis strikes are more likely, or at higher risk, of mortality and experiencing disruptions as compared to the general population. Lack of resources prior to a disaster is only heightened after a disaster. The term vulnerable populations must be applied at the local level and incorporated into every aspect of emergency management; emergency management must be *inclusive*, not exclusive.

Emergency Management Plans for Disaster

Vulnerable populations are disproportionately affected by disasters often having higher mortality rates and the recovery period being longer and more challenging (David et al. 2011). For example, during Hurricane Sandy, it took twice as long for electricity to be returned to the New York City Public Housing Projects than to adjacent neighborhoods where middle to upper class residents lived. A recent, but tragic example, occurred when Hurricane Maria contributed to the deaths of nearly 3,000 people due to the exceedingly slow response and recovery period efforts (Newkirk 2018). The next sections provide information regarding the four steps of the emergency management plan – preparedness, response, recovery, and mitigation as it relates to vulnerable and disability populations.

Preparedness

Emergency management preparedness focuses on how local, state, and federal agencies and organizations can prepare themselves for various disasters. The process of preparedness includes conducting risk assessments, working across agencies and organizations during the planning process, and testing, or exercising, emergency operation plans (Phillips et al. 2017; Bullock and Haddow 2003). According to Bullock and Haddow (2003), preparedness can be defined as, "a state of readiness to respond to a disaster, crisis, or any other kinds of emergency" (p. 115). Emergency preparedness encompasses many activities and levels of preparedness not only for emergency management agencies, but for businesses, service-delivery agencies, hospitals, nursing homes, and the like. Emergency managers, who are tasked with putting emergency operations plans (EOPs) together, should consider forming task forces or working groups to ensure all populations within the community are a part of the planning process.

When working with people with disabilities in the planning and preparedness phases, it is critical that emergency managers consult and work directly with the disability community to ensure that no one is left behind. The disability community is not homogeneous, but rather a diverse segment of the US population that should be included in the planning and preparedness phase of emergency management (Davis et al. 2007). All emergency management municipalities are obligated to ensure accommodations under the Americans with Disabilities Act of 1990 (Davis et al. 2007). Given this requirement, it is recommended that disability organizations and agencies be a part of preparedness and planning. In addition, some studies have shown that the elderly is "less likely to receive warnings than younger persons" (p. 180) as a result of being more isolated, less linked to social networks, and diminished physical and mental abilities (Peek 2013).

Emergency managers need to consider the specific language and cultural needs of the refugee and immigrant community within their locale. Ensuring that networks exist to help disseminate information to the immigrant population can be the difference between life and death. Housing advocacy, homeless agencies and shelters, social services, and community centers should be included in the emergency planning process. Of critical importance is ensuring plans include sheltering and temporary and permanent housing.

Response

The response phase is the critical time period when first responders, emergency managers, and crisis human services workers work diligently in a coordinated effort to provide efficient and effective services during a major crisis or disaster (Phillips et al. 2017). Response may include running shelters, evacuations, emergency room activities, and fire and rescue. Disasters pose specific threats to vulnerable populations as at times they have been left behind or lack access to services that sustain their life.

While some people with disabilities live fully engaged and vibrant lives in the United States, during a disaster or major crisis, their ability to evacuate, sustain life without live-saving equipment, or to process the rapid changes and dangers may be significantly diminished. First responders, emergency managers, and crisis human services workers need to be aware of this potential hazard and be prepared to provide, for example, transportation to a shelter that is accessible, ensure that there are alternate forms of communication about evacuations and the disaster in general, ensure medical personnel are available to assist with medications and other issues as necessary. Old age is often a primary factor in deaths after a disaster (Peek 2013), as was seen with Hurricane Sandy and Katrina. For example, of the 1,300 people who died from Hurricane Katrina, "67% were at least 65 years or older" (Peek 2013, p. 172). Of the 100 people who died in Superstorm Sandy, close to 50% were 65 years or older (Mapping Hurricane Sandy's Deadly Toll 2013).

At times, people living in poverty, including the working poor, do not readily have access to transportation to evacuate or have the means to provide temporary housing during a disaster.

When the World Trade Center towers came down, more than 2,700 people were killed (September 11 Fast Facts 2018). While accurate numbers remain unknown, it is estimated that

there were 100 undocumented workers who also perished that day. Perhaps out of fear or lack of access to language-appropriate materials, the families and loved ones of those workers who were killed did not come forward; nor did officials seek them out (Ruiz 2016). Fear, language barriers, or lack of outreach can prevent individuals from not only being counted but receiving post-disaster services that can help them recover.

Recovery

Recovery is considered the longest stage, or phase, of emergency management. Depending on the type, size, and severity of the disaster, the recovery phase can last anywhere from a few days or weeks to years. Human service organizations and agencies, community and civic associations, and human services departments within emergency management play a critical role in recovery. While communities may never be the same after a disaster, there is always an opportunity to strengthen communities and better prepare them for the next major crisis or disaster. According to Phillips et al. (2017), "After a disaster, we must think about a wide array of concerns that face families, communities, organizations, leaders and managers. Recovery, while daunting, provides an opportunity for these kinds of people and the places that they love" (p. 254).

Housing for some people with disabilities after homes are lost in a disaster is paramount. For example, people who use wheelchairs will need new housing that is retrofitted so they can move about independently. For others, loss of paratransit access prevents them from going to their jobs or even to obtain medical care, such as dialysis. For older people, the risk of not being able to access life-enhancing and/or life-saving medications and services is not the only significant disruption. Older people are also at higher risk of isolation and increased mental health issues than invulnerable people.

Housing post-disaster can be especially challenging for people who were living in poverty (i.e., the working poor) in terms of obtaining temporary or new housing, sometimes forcing them instead to return to homes that were heavily damaged. While aid for the federal or state government can eventually support some reconstruction, often there are delays in housing aid programs, long transportation disruptions preventing access to essential daily activities such as work and school, and housing complexes can remain low on overall rebuilding priority lists. In the aftermath of disaster, one type of funding that can be accessed for older people to use during recovery is the Older Americans Act of 1965 (OAA), which provides grants to states for community planning and services. In addition, the OAA is an antidiscrimination law that classifies older Americans as a legally protected class.

Unfortunately, under extreme situations, poverty can put people at higher risk of death as evidenced by the aftermath of Hurricane Maria. According to a research study conducted by George Washington University (2018), "The results of our analysis of total excess mortality by socio-demographic subgroups show that every social stratum and age group was affected by excess mortality. However, the impact differed by age and socioeconomic status. The risk of death was 45% higher and persistent until the end of the study period for populations living in low socioeconomic development municipalities, and older males (65+) experienced continuous elevated risk of death through February" (p. 7).

For non-native English speakers, and people from different cultures or religious backgrounds, the recovery process can be more challenging and isolating, as indicated in the prior section on response. Ensuring safe spaces to receive services and translated materials and interpreters on hand can help dissolve barriers. In addition, working with refugee and immigrant organizations can assist with communication strategies and dissemination of information as well as provide valuable information and resources (Tierney et al. 2001). Often, refugees and immigrants have residual health conditions and mental wellness considerations that are a direct result of their experiences either being forced to flee their homeland (as in the case of refugees) or seeking safety and economic security (as is often the case with immigrants) (Mincin 2017). Emergency management and recovery workers need to be aware of these types of issues in order to appropriately treat them.

Mitigation

According to Bullock and Haddow (2003), mitigation is "a sustained reaction to reduce or eliminate risk to people and property and hazards and their effects" (p. 37). Mitigation is distinguished from the other phases of emergency management because it focuses on long-term efforts at reducing risk (Bullock and Haddow 2003). Preparedness, response, and recovery are focused on how the emergency management and first response community will be ready for, respond to, and recover from disasters. Mileti (1999) explains mitigation as "the policies and activities that will reduce an areas vulnerability to damage from future disasters" (p. 23). In many ways, mitigation includes the concept of community capacity building and resiliency. Working with vulnerable populations before, during, and after disasters offers the opportunity to not only ensure they are *included* in all phases of emergency management and that their specific needs are voiced and met, but to also build stronger, more resilient communities (Tierney et al. 2001).

Universal design is one example that can be considered a mitigation measure for people with disabilities. Universal design refers to ensuring equal access to all people. This may include ramp entrances to buildings, curb cuts on the street, and flashing alarm lights in the hallways of buildings. They are considered universal because the designs both meet the requirements of making things accessible to people with disabilities under the Americans with Disabilities Act of 1990 and can assist people in the "general" or nondisability community. Curb cuts on streets enable people in wheelchairs to move freely about a city or town. It also helps parents and caretakers move children in strollers freely around town. Likewise, flashing fire alarm lights assist people who are deaf know how and when to evacuate a building as well as the "general population." Mitigation strategies can help to reduce death and disproportionate negative effects of disasters on the aging population (Fernandez et al. 2002; Peek 2013). Strategies include shoring up social networks to reduce isolation and increase communication dissemination and ensuring strong infrastructure such as shelters designed for assisting older people (Fernandez et al. 2002).

Mitigation projects for lower-income communities may include strengthening structural aspects such as buildings, electrical grids, and community organizations. Mitigation efforts for the refugee and immigrant communities can include conducting assessments with the help of refugee and immigrant organizations so that education and networks can be put in place. Communities can become stronger and more resilient by seeking to better integrate refugee and immigrant people in their towns and cities.

Conclusion

This chapter provides an overview of how people with disabilities and vulnerable populations might be affected during and after a disaster. Understanding the preexisting conditions such as poverty, disability, and language barriers can assist greatly when responding to and recovering from disasters. In addition, emergency managers can and should reach out to local community, advocacy, and service-delivery organizations and include them in emergency planning, drills, and exercises. These individuals and organizations know the issues and needs of specific populations and can play a significant role in the well-being of your community when disaster does strike. Although not all vulnerable populations are always legally protected, such as people living in poverty, it is critical for emergency managers to robustly include these populations in all phases of emergency management to mitigate loss of life and facilitate speedy recovery. Further, people with disabilities and the aging are legally protected classes and must be incorporated into all phase of emergency management planning and response. People with disabilities and functional needs as well as other vulnerable populations are at increased risk for long-term recovery disruptions and higher rates of mortality during and after disasters. Finally, emergency managers need to ensure accessibility during and after a disaster. Often lack of accessibility unnecessarily creates increased dependence. For example, someone

maybe in a wheelchair and function fine regarding daily living. However, during and after a disaster, maybe become dependent because disaster assistance centers and/or shelters are not accessible. Inclusion is the key to ensuring vulnerable populations are safe during disasters and recover well after the disaster.

EU Private Security Regulation

Spyridon Triantafyllou
John Jay College of Criminal Justice, New York, NY, USA

Keywords

Private security · Security industry · Regulation · EU

Definition

Legislative act to harmonize private security industry across the European Union.

Introduction

The European Union (EU) law is divided into "primary" and "secondary" legislation. The treaties (primary legislation) are the basis for all EU action. Secondary legislation – which includes regulations, directives, and decisions – are derived from the principles and objectives set out in the treaties. A "regulation" is a binding legislative act that must be applied in its entirety across the EU. A "directive" is a legislative act that sets out a goal that all EU countries must achieve. However, it is up to the individual countries to devise their own laws on how to reach these goals (European Commission).

To date, there is not such legislative act regulating the private security industry meaning that there is no harmonization of the industry of all the EU member states, apart from certain security services which are partially regulated. For instance, the Regulation (EC) 300/2008 has established rules in the field of civil aviation security aimed at protecting persons and goods from unlawful interference with civil aircraft (European Commission).

However, regulation is necessary because private security employees across the EU should act with professionalism and high-level standards. The critical issues for regulation might be synopsized in the following: age, experience requirements, licensure, personal character, and education and training needed (Nemeth 2012).

Why Regulate?

The private security industry is a very diverse industry encompassing a variety of products and services. Private security personnel are not like ordinary citizens, while many security-related occupancies draw upon special privileges (i.e., detainment of shoplifters, use of force by door supervisors, armed by security guards in cash-in-transit vehicles, access to information which might be exploited or abused). If minimum standards are taken away, there is a temptation to lower standards to win business with all the

potential implications that has a poorer quality security sector (Prenzler 2012).

Regulation of private security industry in the EU is of the utmost importance on the political agenda. On the one hand, it is essential to regulate and improve professional standards given the increased needs of public police force, the increased risk of terrorism, and the mundane problems of crime prevention and policing, assuming the overall low standards and widespread problems (Button 2007).

On the other hand, regulation is an important factor for optimizing security, as it needs to adapt and be responsive to meet the changes in the industry, but it should also face the regular challenge of balancing consumer, industry, and public interests (Prenzler 2012). Besides, regulation must be tailored to enhancing private security and not hindering or smothering it, which can occur (Button and Stiernstedt 2018). Consequently, the main question about private security industry in the EU might be synopsized as: do we need *regulation, deregulation, or reregulation?*

The Landscape of Private Security in the EU

A recent motion for action of the European Parliament highlights the value of regulating the private security industry. Specifically, it is mentioned that "*(. . .)* D. more than 1.5 million private security contractors were employed in around 40,000 private security companies (PSCs) in Europe in 2013; *(. . .)* the turnover of these companies in that year amounted to around EUR 35 billion; *(. . .)* K. a legal framework with binding regulatory and monitoring mechanisms should be put in place at international level to regulate their use and provide sufficient control over their activities; *(. . .)* whereas the current regulatory situation in this sector comprises a series of inconsistent rules which vary enormously between the Member States; *(. . .)* P. the European Union does not have a regulatory framework of its own, *(. . .)* Q. whereas it is of vital importance to prioritize the establishment of clear rules for interaction, cooperation and assistance between law enforcement and private security companies; *(. . .)*" (European Parliament 2017).

Several reports and papers underline the dizzying and complex variety of standards relative to regulation by citing the statutory laws of several member states or other statistics and thus conclude the lack of uniformity of standards EU wide (Button and Stiernstedt 2018). Identifying the level of analysis is crucial when discussing the standards relative to regulation in general.

Focusing on the European Union, discussion is expected to deal with national and supranational levels of governance. One of the most important aspects of private security regulation is that instead of protesting about state regulation – as most commercial sectors do – many sections of the private security industry have actively welcomed state regulation (White 2010). Furthermore, regulation has become a way of increasing the presence of state structures in the security marketplace so as to render private security services more "state-like" (Smith and White 2014). But the scope of this analysis is limited to the EU context, despite the fact that regulatory issues about standards of private security system are mainly addressed by the member states.

According to rulings of European Court of Justice, the private security industry is considered an economic sector of the EU and, therefore, falls under the regulation of the internal market (Born et al. 2007). There are also other issues that may affect further regulation of private security industry in the EU while at the same time making imperative the need for adopting a new EU private security regulation.

According to Directive 2006/126/EC, security services are considered just another services in the open market, notwithstanding the particularity of the industry as mentioned above. This essentially means that from the supranational point of view, the private security companies will never be fully able to function in transnational level without disastrous consequences for the standards of the industry, since there is not a homogenous field in European level setting minimum standards for their action. Besides, the question of sovereignty does impact on the tendency for more integration of the private security industry. Again, an attempt

to harmonize this field should be welcomed as means to raise the standards of the industry EU wide (Loxa and Siagkou 2016).

Finally, assessing the Europeanization of the industry, three dimensions should be taken into consideration: (a) the possible *market failures*, affecting the trustworthiness of the sector and hampering efficient private-public collaboration strategies (i.e., the existence of false independent contractors, unfair dumping of prices, high competition can create a dysfunctional balance between supply and demand of security services), while an antidote for the regulatory power of the single market might be European Quality Standards; (b) the *creation of EU minimum guidelines* regarding private security across the EU member states is directly aimed with legislation (i.e., requirements for training, licensure, control); and (c) rethinking *European or international collaboration strategies*, emphasizing on the fact that the private security sector must strengthen its ties with European institutions (Pashley and Cools 2012).

Pertinent to this contribution are the following documents: the "Handbook State Regulation Concerning the Civilian Private Security Services and their Contribution to Crime Prevention and Community Safety" (UNODC 2014), the "Private Security Services in Europe Facts & Figures" (CoESS 2011), and the "Security regulation, conformity assessment and certification" report for European Commission (ECORYS 2011) (*see* Further Readings).

Conclusion

The rise of private security industry across the European Union and the different level of industry regulation in each and every Member-State have made imperative the adoption of an EU regulation. However, such legislation has not passed yet, despite any political implications and the increasing size and needs of the industry in the context of single market. Some initiatives on behalf of EU organs have already mentioned reflecting the importance and the potential of private security to the overall security of the EU. It remains to prove that the in-name-only "EU Private Security Regulation" will actually become a reality across the Union and not remain merely pious hope.

Event Security

Mark Camillo
Security, Fire and Emergency Management, John Jay College of Criminal Justice, City University of New York, New York, NY, USA

Keywords
Celebratory event security · Commemorative event security · Diplomatic event security · Entertainment event security · Festival event security · Mass gathering event security · Religious event security · Special event security · Sporting event security

Definition

For the purposes of this unit, event security can be defined as the plans, design, and implementation of measures required to create and maintain a safe environment for a planned event that includes attendance and participation of a private or public nature.

Introduction

Physically securing events is not a new phenomenon; however, over the past 20 years (1998–2018), the globally accepted approach has evolved into a methodology where all hazards of a reasonable nature are factored into the security plan. This topic will be addressed in a manner that allows the reader to gain an understanding of the potential risks which could cause a disruption to an event, how securing an event should be accomplished, and the potential consequences event security managers much consider, such as postponing the event to experiencing a crisis where death and/or serious physical injury to those on site is likely to occur.

Types of Events

Events that warrant securing have historically fallen in several categories that include but are not limited to:

- Entertainment (e.g., music festivals, concerts, and parades)
- Ceremonial (e.g., college graduation commencement)
- Sporting (e.g., Olympics, FIFA World Cup)
- Faith-based (e.g., the Hajj to Mecca)
- Diplomatic (e.g., G7 Economic Summit, US Presidential Inauguration)

Events such as the examples listed above are not unique to one particular country or culture. These events are generally social in nature, with an announced time and place. The size of attendance is often driven by the type of event. For example, a college graduation commencement may take place depending on the size of the graduating class and audience scheduled to participate and attend, respectively. Similarly, an entertainment event may take place at a venue considered large enough to appropriately host the anticipated patrons. Sporting events such as golf require an approach different than a stadium due to the expansive nature of the area where the competition takes place. No single approach to securing an event can be duplicated without tailoring it the unique nature of the event. Many security components do have general application; however a review of previous security plans for similar events is recommended to compare and adopt or dismiss based on any unique needs of the upcoming event.

Event Venue Nomenclature

Back of the House (BOH)

This term is likely sourced to eating establishments and performing arts venues. The "back of the house" (BOH) is often referred to the areas where workers, talent, equipment, product, etc. are entering or produced in the venue. General public or ticketed public do not normally enter the venue from back of the house entrances. This is an important reference term to remember when creating an event security plan.

Front of the House (FOH)

This term is applied to where the public or invited guests enter the venue during scheduled event times. The front of the house (FOH) is where crowds both enter and exit an event unless event operations open additional exits at the conclusion of an event.

Building an Event Security Plan

Risk Determination

Threats Versus Hazards

It is very important to distinguish how an event may be of risk. A threat is generally understood to be of a man-made nature, where a hazard is a result of a natural occurrence (e.g., blizzard, earthquake, wildfire, and flooding). Both threats and hazards must be factored into the design and development of a security operation.

> Many security professionals and their clients confuse threats and hazards. Hazards can be either natural or man-made and are generally unintentional or without malice. Threats are always man-made and intentional and with malice. (Norman 2016, p. 111).

Threats may be detected and deterred through preventative countermeasures. Natural hazards such as severe weather are not likely preventable, but mitigation measures and emergency response protocols can be put in place in advance to lessen the chances of damage to property or personal physical injury. Regardless of the potential danger that has been identified, the level of risk must be predetermined in order to effectively mitigate hazards or counter threats.

Before determining the degree of risk faced by an event, assessing the contributing factors that will constitute the risk is prudent. Today's security professional understands the importance of conducting a risk assessment of an event and the environment of which it will take place. When conducting the initial assessment, it is recommended that all physical vulnerabilities be identified.

Vulnerabilities

Vulnerabilities would be simply described as where "gaps" are identified in the perimeter that threat actors might exploit the operational environment. Access points that are controlled both on event day and nonevent day are considered positive elements to securing a venue. Due to spectators or attendees that arrive on event day prior to the scheduled event, gates or predetermined entrances for crowd access must be critically examined for placement of security personnel and equipment. Due to the spectrum of security measures that may be deployed at events, these access areas must be able to accommodate the security screening and ticket-taking if they are co-located. All perimeter fencing must be examined to ensure it is intact and is of the correct design, height, and strength to deter a threat actor or unauthorized person from accessing the event. A strong event security plan can only be achieved with prevention and protection measures in place. The vulnerability assessment should identify all weak areas to be addressed before the event.

> After fully understanding the operating environment, note any physical security vulnerabilities that could be exploited by threat actors in this operating environment. These may include unintended access points; abuse of normal access points by stealth, trickery, or intimidation; and types of assets any threat actor might be interested in. (Norman 2016, p. 93).

Threats

In addition to a vulnerability assessment, a threat assessment must also be conducted to determine any negative interest a person or group might direct toward the event. This includes their threat vector

or path and tools used in the attack. Threats may emanate from groups or individuals. Intuitively, threats are likely to originate from outside an event venue, but a comprehensive threat assessment must include the "insider threat." This type of threat actor may be already employed by the venue or a company under contract to provide services to the venue and/or event. Many companies are brought together, particularly in sporting and entertainment events, to bring the event to a successful conclusion. Not requiring "in-house" organizations and contracted organizations to conduct background checks on their employees before working an event creates a porous threat environment. The overall "workforce" at an event must be factored into the threat picture. Outside threats can source from hate groups, criminal enterprises, and extremist groups to name a few.

Consequences

The final area to factor into a risk assessment of an event is the consequences, or negative impact of an incident. Prominent examples would be the devastating effects caused by natural disasters. In the context of analyzing risk for events, this would include severe weather. Outdoor events in particular such as sporting competitions and parades can sustain considerable property damage and potential injuries to participants and attendees if the consequences of a severe weather event are not factored into the overall risk mitigation plan.

> Weather should factor in your risk assessment, and you should come up with contingency plans for your various 'what if' scenarios. For example, you might be hosting a celebrity golf tournament that will attract thousands of visitors. What contingency plans must you have in place if there is a sudden violent thunderstorm with hundreds of spectators seeking cover from lightning strikes under the trees? You must have the capability of being alerted in good time of approaching storms, and all stewards must be fully aware of what action to take should the need to evacuate the course arise. (Walton and Philpott 2011, p. 10).

Capabilities Determination

The fundamental needs in achieving an effective event security operation require addressing requirements in the areas of people, process, and technology. In a perfect scenario, the event security planner would have access to skilled personnel and a variety of physical security countermeasures. Essential training of personnel would not be an issue and would include skill development in areas such as:

- Patron screening equipment operation and techniques
- Bag search techniques
- Hostile surveillance detection

The cost of equipment would also not affect the overall budget of the operational security plan. All elements in place would be driven by a seamless process that ensures operational readiness. This is of course not reality.

Event security is unique in that crowd flow and the amount of time allotted for admittance before an event will drive the design of screening at entrances and the items permitted into the event. It is important to clearly understand any limitations placed on entering patrons by the event organizer or host venue. Prohibited items posted on signage outside the venue and on the event website have proven very effective in reducing the number of prohibited items identified by screeners at the entrance gates. An example would be liquids. Some events allow bottled water, while other events do not allow any liquids unless for medical/health purposes. Limiting items and the size of bags entering an event may reduce baggage screening to visual searches by event security personnel. This is, however, not as effective as a bag of any size being searched by a trained event security screener.

Event Access Control

Those responsible for determining the level of access control effectively control the event. Planned and/or scheduled events are well-advised to implement ticketing for access during the scheduled event. Internal areas require credentials to provide access for authorized individuals who are permitted to enter restricted areas. Credentials are issued to various groups to include workers, special guests, and entertainment groups.

Credentials do not supersede the physical screening measures outlined below. Everyone entering a venue whether they are spectators or engaged in a working capacity must be screened to ensure consistent protective measures are in place at the venue.

Ticketing and Invitations

Events with no restriction regarding who is allowed to enter can be conceptualized as having a host of potential issues. Among the top concerns would be the inability to determine in advance the amount of space required to safely assemble the attending crowd. This creates challenges especially for both event security providers and public safety entities who develop their deployment plan of personnel and equipment based on projected crowd size. A ticketed event or event that restricts attendance to a predetermined guest list allows for a properly staffed and equipped event security operation.

Patron Screening

This is a critical component in an event security operation. Whether the term used is patrons, attendees, or spectators, the front of the house at the venue is where patrons should be screened at the level determined by the venue or the affected authorities. Generally, sporting leagues have recommended best practices that include the level and types of screening. The type of event may drive the level of patron screening. Some venues maintain a consistent level of screening regardless of the event. Screening equipment and techniques to consider would be:

- Walk-through metal detectors
- Handheld metal detectors
- Pat-down searches

Patron screening is recommended to be positioned outside the venue if possible or minimally at the venue entrances.

Bag Search Screening

This critical element is dependent on any size or style limitations set forth by the venue or sanctioning body, i.e., sporting league or conference. Tables positioned in immediate proximity to the patron screening operation allow for patrons and their belonging to be checked in a manner that eliminates items to be discretely moved from the patron to the bag or vice versa. Items of an illegal, prohibited, or suspicious nature should be immediately brought to the attention of nearby authorities. It is recommended that bags be visually inspected and, when a questionable item is observed, the patron be requested to remove the item and place it on the table.

Vehicle Screening

Vehicles permitted to enter the back of house delivery areas, i.e., loading dock or adjacent parking lots within the established venue perimeter, would be screened in accordance with the back of the house section of the event security plan. Setback is a term used to describe the distance between public areas and entrances to the venue. A properly designed perimeter plan includes creating as much setback as reasonably possible. Urban-situated venues often have minimal setback due to the dense streetscapes surrounding the venue. Regardless of the setback from public streets and sidewalks, it is recommended that an access control checkpoint be established with anti-ramming technology in place. Vehicle and occupants should be on a preauthorized list in order to enter the venue grounds. The manner in which vehicles are screened should be in accordance with venue-approved improvised explosive device protocols or defer to on-site public safety personnel assigned to perform this function. Optimally, all vehicles such as delivery trucks and team buses should be screened prior to entering the venue. An exception might be team buses coming from a secure location such as an airport. They are generally permitted to enter with a police escort that has ensured the integrity of screened buses.

Event Exterior Concerns

Ingress Crowd Flow

The density of the crowd assembling to enter a security checkpoint can be an inviting target for attack. Threat actors can weave their way into the crowd and achieve their objective using items such as small firearms, improvised explosive devices, or even edged weapons.

Suggested Countermeasures

- Add surveillance detection officers on the exterior out front of the entrances on event day to look for inappropriate or pre-attack behavior.
- Coordinate with your local law enforcement agency to determine if they have officers assigned to detect hostile surveillance or pre-attack behavior.
- Work with both your local law enforcement agency and recommended private security companies to have specially trained K-9 teams that can detect vapors emitted by individuals carrying or wearing explosive materials.

Egress Crowd Flow

Patrons exiting after an event naturally move in mass, thereby creating another crowd density situation. A threat actor only has to "swim upstream" far enough to find the crowd conditions attractive enough to carry out a malicious act, with no intention of entering the building. An example of this type of attack would be the one that occurred in May 2017 at the Manchester Arena, England, following a music concert by American singer Ariana Grande. A suicide bomber detonated a backpack improvised explosive device (IED) in an area outside the arena accessible to the public (Manchester Evening News 2018).

Suggested Countermeasures

- Extend your event security coverage to redeploy personnel outside the venue to ensure any barriers set up to manage the egress are not compromised.
- Coordinate with law enforcement to ensure uniformed officers are positioned at and near the exit points to detect and/or respond to suspicious behavior exhibited by persons observing exiting patrons.
- Extend the assignments of your canine explosive detection teams to be patrolling the periphery of the venue for potential threat actors carrying or wearing explosive devices.
- Ensure that the exterior perimeter plan developed by you and law enforcement extends from your venue to adjacent mass transit stations such as trains or subways.

Ramming Vehicles

As we have sadly seen at recent global events, the determined attacker may resort to driving a vehicle at a high rate of speed into a crowd capitalizing on their vulnerability when outside the venue.

Suggested Countermeasures

- Survey the walkways connecting to your venue to determine if vertical posts known as bollards are positioned in a pattern that prevents a passenger vehicle from accessing the sidewalks from a street. Fixed metal posts are known as traffic bollards, but temporary barriers can also be purchased or leased to fill any gaps. Collapsible or retractable bollards are a good choice for back of the house locations such as loading docks.
- Coordinate with law enforcement counterparts to determine where large vehicles such as trucks or buses may be parked to temporarily block vehicle access on event day.

Artist Security

Entertainers also referred to as the "talent" are susceptible to injuries while performing. Some incidents to consider within the venue would be:

- Accidents or assaults involving talent
  - Artists injured due to slips, trips, and falls
  - Artists grabbed or pushed by patrons
- Stage collapse
- Lack of properly positioned and staffed movable barricades for crowd management

Active Shooter

Properly implemented security countermeasures noted in the Event Access Control section should significantly mitigate the chances of a patron entering into an event site with a firearm. However, at outdoor (open-air) events, an active shooter situation occurring outside the venue is plausible. Targeted areas can include ingress/egress areas at an event site, parking lots adjacent to an event site, or locations at a distance that offer a clear vantage point. This is known as a standoff threat. The mass shooting spree that occurred in October 2017 in Las Vegas, Nevada, during an outdoor music festival exemplifies the possibility of an active shooter targeting concert-goers from a

location that is far from the event site (Las Vegas Strip Shooting 2017). This threat cannot be mitigated without public sector involvement, law enforcement in particular.

Suggested Countermeasures

- Employ hostile surveillance teams at locations outside ingress and egress points of the venue to identify and alert authorities when pre-attack behavior is detected.
- Coordinate with law enforcement counterparts to determine if a counter-sniper plan and assets are in place due to locations at a distance that might offer a shooter to clearly target patrons.
- Offer security personnel to assist law enforcement in posting vantage points of concern for the purpose of observing and reporting the presence of a potential threat actor.

Crowd Behavior

The behavior of a crowd, particularly at music concerts and festivals, should be factored into the overall event security plan. Crowd management must prioritize protecting the crowd from the crowd. Some of the activities and situations to prepare for that are associated with music festivals include:

- Mosh pits (rough physical activity by concert-goers in front stage area) (Mosh Pit Definition 2018)
  - Injuries to concert goers and event staff possible
- Crowd surfing (concert-goers physically passed overhead in a prone position) (Crowd Surfing 2018)
  - Injuries and unwanted touching can be the consequences.
- Intoxication (this has both health and legal implications for intoxicated fans)
  - Arrest for alcohol intoxication and serious physiological reactions possible
- Illicit drug use (combined with alcohol increases chances of overdosing) (Illicit Drugs at Music Festivals 2018)
  - Amnesty boxes are often positioned at screening areas to offer patrons an option of disposing of drugs before being screened or bags searched.
- Crowd density (mass gathering without metering or evacuation measures can escalate if not monitored to conditions with catastrophic consequences) (Love Parade Music Festival 2018)

A complete event security plan has event security staff prepositioned between the performance areas and the crowd as well as in key areas to ensure movement of crowds to reduce crowd density that occurs due to overloading of stage-front viewing areas. Event personnel are often positioned in the "pit area" which is located between a standing crowd of concert-goers and the stage. Security personnel who work in this area during concerts are often referred to as the "pit crew."

The Importance of Collaboration and Coordination

Event security planners cannot create an effective plan in a vacuum. It is imperative that all key stakeholders ranging from venue management to assigned public safety agencies collaborate on the plan. Some may have different objectives, but all share a common goal of having a safe event.

Conclusion

Events, large or small, potentially draw negative attention. Tactics ranging from small-scale attacks to deploying weapons of mass destruction all fall within the threat spectrum. Be ready by being prepared and resourceful. The threat actor only has to get it right once. You must get it right for every event.

Definition

Executive protection is the protection of a human asset against harassment, injury, death, and embarrassment.

Introduction

Executive protection is a specific and unique area of the security industry. It is primarily responsible for safeguarding a person against harassment, injury, death, and even embarrassment. Executive protection is also a highly sensitive security assignment that not only requires the executive protection professional to ensure the safety and security of the executive but to maintain strict confidentiality and professionalism (June, 2008). This chapter describes the basic fundamentals for providing executive protection security for an executive and should be used as a foundation for a structured and comprehensive close-protection security model. Most executives are part of an organizational structure and, as such, require protection because of their senior leadership position and/or affluence. Executive leaders are considered top decision-makers; and if they are incapable to lead or make decisions for their organization, it can affect the executive's reputation, credibility, and even its stock price of the organization. The truth is many executives do not fully understand the role and responsibility of the executive protection professional (EPP). Executives often view the executive protection professional as someone who needs to be available if an emergency or crisis was to occur; however, the executive protection professional is much more than that.

Executive Protection: The Tough Road Ahead

Some executives are apprehensive and do not always appreciate the executive protection professional interfering or monitoring their movements or personal space. While some executives believe that they can take care of themselves without assistance, others may be ridiculed by colleagues for having (and feeling as though they need) security. All of these concerns can have a negative effect, not only on the executive protection professional but on the ability of the executive protection

professional to ensure a safe and secured environment for the executive.

Effective and robust executive protection programs must be developed, analyzed, and implemented based on threats, vulnerability, risk, and a *willingness of the executive to participate in the security program.* This productive approach can identify challenges and obstacles, which must be addressed if an effective and efficient executive protection security program is going to be successful. It can also identify areas that may need additional strategic security planning towards maintaining the highest standard of personal safety and security for the executive (June, 2008).

A primary responsibility of the executive protection professional is to limit the amount of risk exposure to the executive using sound and productive security and risk reduction strategies. The executive protection professional must incorporate all available security functions and methods, while continuously assessing all relevant data relating to all threats, vulnerabilities, and risks. It is critically important that the executive protection professional understand the overall risk analysis and apply security and protection strategies based on the probability of an incident occurring.

The executive protection professional must also be able to maintain an effective level of security, while ensuring a level of "comfort and normalcy" for the executive. Though, this is easier said than done, the executive protection professional must attempt to "strike a balance" between security and the ability of the executive to move freely and not feel hindered or restricted. Many close-protection security personnel fail when beginning their careers because of the assumption that the executive fully understands what personal protection is and how it must be conducted. Unfortunately, many executives utilizing a close-protection professional (same as the executive protection professional) do not understand how protection security should be applied and demonstrated.

Executive protection security has evolved into a more contemporary form of specialized security. It is both an exciting and demanding responsibility within the security industry and will require a commitment of professionalism, diligence, and integrity. The executive protection professional must be highly trained and well-equipped to handle the enormous responsibilities that will be entrusted to them by the executive. It will require extensive and continuous theoretical and technical training, which will be needed to confront the many current threats that executives face around the globe today.

Historically, protection personnel were exclusively chosen for the private sector from federal agencies, such as the United States Secret Service, United States Department of State, the military, and from municipal police departments because of their past training and experience. The advent of commercial close-protection training schools has elevated the civilian population towards filling the ranks of corporate organizations towards addressing their executive protection security needs. Many private organizations now utilize close-protection professionals to perform executive protection services for senior leaders as a preventive mechanism to ensure resilience, asset, and even brand protection (West 2018). The ability to ensure the personal protection of an executive can provide reassurance to a company and its stockholders. This is considered part of a robust and effective protection strategy.

The executive protection professional will continue to provide personal protective security services across a broad spectrum of threats now and in the future. Throughout the decades crime and violence have increased across the globe, to include violence in the workplace. Active shooter incidents, assassinations and attempts, as well as kidnappings have led to injury and death for many executives. These incidents have all contributed to the growing concern and need for specialized professionals trained in protection security. Private organizations have recognized the value of having an executive protection security program as it provides a safe environment for the executive, while reducing the overall risk levels associated with both professional and personal activities (Dale 2008).

The executive protection professional has evolved from a reactionary figure to a proactive and strategic planner. Known as *areas of concentration*, the executive protection professional can develop and implement sound and productive strategic planning for personal protection, motorcade security, site advance, physical security for primary assets, first-aid, counter surveillance, and threat and risk analysis for the executive. The executive protection professional must be proactive in assessing and countering incidents that can hurt or embarrass the executive. This can be difficult to accomplish in all environments, especially when the executive is reluctant to work with the executive protection professional in following the security recommendations.

The main responsibility of the executive protection professional is to remove the executive from the danger zone using a *cover & evacuate (C&E)* method (Dale 2008). The executive protection professional should always focus on prevention and the avoidance of trouble rather than confronting it. An effective executive protection professional providing executive protection security must be able to analyze the environment for potential trouble before it starts. This can be accomplished by experience and the executive protection professional maintaining continuous levels of training in order to remain effective in this role.

Comprehensive security planning is critical for protecting the executive; however, overwhelming the executive with convoluted security models and procedures can equally fail because of frustration on the part of the executive. The executive protection professional must provide a safe environment for the executive that is not intrusive, overwhelming, or hindering as this milieu can result in confusion and possible conflict between the executive and the executive protection professional. This directive can also help in ensuring the security plan is not only approved but embraced by the executive.

Setting a professional standard early on will ensure the executive protection professional and the executive understand what is expected and what is not tolerated. The executive protection professional must be respectful and professional while maintaining the primary role as a protection professional. The executive protection professional must have both hands *free* at all times and remain disciplined as to not violate this important rule. In particular, allowing and accommodating the executive's requests for carrying packages or holding personal items will result in the executive protection professional becoming disengaged, hindered, and not focused (Oatman 2006). The executive protection professional certainly has many challenges ahead, but maintaining professionalism and adhering to the primary principles of close-protection security can result in an effective and efficient program.

Protection Site Advance

Comprehensive and effective site advance is needed to ensure the location the executive is visiting is safe. It requires conducting comprehensive security planning that identifies vulnerable areas at the location. This critical measure is part of a robust executive protection security plan that provides the necessary security and safety steps to stop an attack on the executive; as well as protect the security team.

Advance work also requires the executive protection professional to conduct motorcade route surveys to ensure the quickest and safest way for the executive to get to the location. A threat assessment can help identify dangerous areas in and around the location the executive is visiting. If the location presents security and safety concerns for the executive and the security team, the executive protection professional conducting the site advance must relay that information immediately to the security detail and/or the executive. Effective site advance requires the executive protection professional to arrive at a location at least one hour prior to the executive. Checking for protesters, suspicious individuals, and/or dangerous conditions both outside and inside the site should be performed and corrective action taken. This important responsibility can help in preventing harm or embarrassment to the executive (Oatman 2006).

A checklist is a useful tool, but it must be reviewed continuously, updated, and based on current threats to ensure the executive protection professional is providing a comprehensive and effective security environment for the executive. Site advance checklists are universal and can be found in most close-protection textbooks or other on-line publications. The executive protection professional must also coordinate with host committee staff to verify the activities that will take place when the executive arrives. The executive protection professional can request help from both security and engineering staff at the site to obtain critical information on the location.

The site advance should be outside for the arrival of the motorcade and wait for the executive to exit the vehicle. The advance must now escort the executive and the security detail, if assigned, into the location and directly to their meeting area. When the executive is situated at the location and no ongoing threats or problems exist, the site advance should move to the next location based on the executive's itinerary to conduct the next site advance for the executive.

Protection Intelligence

Protection intelligence requires the gathering of all information either directly or indirectly relating to the executive or the location being visited. This is important because it can help the executive protection professional analyze and formulate an effective security environment towards reducing the overall risk level against the executive and EPP team (USDS 1997). The information can be gathered from direct, open, or paid intelligence sources and can help in the assessment of the overall security planning for the executive. The information should be continuously updated, analyzed, and used to direct the necessary security changes towards addressing all threats and risks. The executive protection professional must conduct regular and comprehensive analysis of all information affecting the executive, make recommendations to the executive regarding security and safety changes, and implement the strategies as needed.

Threat Assessment: Calculating the Risks

A primary tenet of close-protection is conducting a comprehensive threat assessment. An experienced executive protection professional knows it is difficult to determine what level of protection security is needed unless a complete and current threat and risk assessment is conducted. Many close-protections professionals believe that threat assessments as well as risk assessment are universally interchangeable. They are not, and mistakenly applying them can result in increased exposure and/or frustration for the executive. It can also result in increased costs, which will be scrutinized.

A threat assessment will be needed if the executive protection professional wants to successfully develop a comprehensive executive protection security plan. Providing the same level of protection security for all environments can be both dangerous and not very cost effective. The threat assessment can identify potential dangers that the executive and the security team may encounter. This can help towards formulating a more specific security plan for the executive. In any case, when tasked with developing a threat assessment, the executive protection professional must gather as much information as possible on the person(s) who may have an interest, motive, intention, and, more importantly, the capability of mounting an attack on the executive.

Gauging the possibility of a potential threat is critical to the protection of the executive and the executive protection professional (Blankchtein 2013; Holder and Hawley 1998, Kobetz 1991). Mentioned in the *Protective Intelligence* section, the information must include current data and other sources of information pertaining to the executive and his or her family. Analyzing open source information, as well as known threatening communications received, can help in calculating a comprehensive threat assessment. Unfortunately, there is no one descriptive profile of an attacker. Assassins vary by gender, culture, and intelligence. An attacker may engage in familiar behaviors and actions before they attack. These steps have visual characteristics that can be observed by the

executive protection professional. These steps would most likely include acquiring a weapon, surveying security near the executive, and the development of a written attack plan. The executive protection professional must remember that developing a strong and effective threat and risk-assessment plan must also include budgeting and acceptance by the executive who must follow the plan (Dale 2008).

Close-Protection First-Aid

The executive protection professional must be trained in first-aid if the executive is injured or becomes ill. First-aid must be part of a comprehensive executive protection security plan to provide immediate medical treatment in the event of an attack, a medical condition, or an accident. First-aid includes CPR, as well as blunt and penetrating trauma injury response. The executive protection professional must be certified in the first-aid and should be recertified annually. The executive protection professional should be familiar with and know the locations of area hospitals, especially hospitals designated Level-One Trauma centers. The executive protection professional must be familiar with any medicines or medical conditions the executive has to advise emergency room physicians when needed (Dale 2008). Medical conditions, medicines, and other important information pertaining the health of an executive should be known by the executive protection professional. This is especially important for international travel where medical services are limited. The executive protection professional must assess and investigate medical services in countries outside of the USA.

Operational Security and Close Protection Terminology

Close-protection security uses specific terminology to ensure confidentiality and security for the executive, the executive's family, and the security team. Exposing specific addresses, names, and activities can be very detrimental to the executive and the executive protection professional as it can alert a potential attacker where the executive is located, the time of the executive's arrival, and what activity will take. The executive protection professional should utilize "code words" that are changed regularly to ensure that any criminals or potential attackers cannot obtain sensitive information that could help in executing a successful attack, including kidnapping the executive. Operational security also includes strict security measures to safeguard all information on the executive and family members. History has shown that the use of confidential *codes names* can reduce the overall risk level, thus reducing the potential for danger to the executive and the executive protection professional.

Formations: A Tactical Approach to Close-Protection

It is likely that the executive may at some point be the target of an attack, whether by gun, knife, or even a whipped cream pie. If the executive is confronted, injured, or embarrassed, the executive protection professional has already failed. The executive protection professional's ability to perceive and identify danger will be in question and re-training will be needed barring termination.

Tactics are available that the executive protection professional can use to protect the executive. Constant vigilance must be used by the executive protection professional at all times. A primary tactic used for the protection of the executive is known as "*Arms-Reach.*" Situational awareness by the executive protection professional that a gun or other weapon has been produced in the presence of the executive is critical. The primary tactic of the executive protection professional is to "cover" and "evacuate" the executive away from the threat environment. If the attack is from an object that is thrown, i.e., a brick, an egg, or a liquid, the "Arms Reach" method still applies and "cover" and "evacuate" is

needed. The executive protection professional should remove the executive from the area and proceed to a safe room or the motorcade.

Responding to an attack requires information that helps the executive protection professional know where the threat is and which direction the executive protection professional and the executive can evacuate. The use of the *"clock method"* to identify the location of a threat is an effective method used successfully. The 12 o'clock position consists of identifying a fixed object on a wall. If an attack occurs, or a weapon is produced, the executive protection professional using the clock method should identify the threat from its position in the clock. For example, if someone produces a knife at the nine o'clock position, the executive protection professional should alert the security detail, by sounding off "knife, 9 o'clock." The executive protection professional with the executive should now cover and evacuate the executive towards the 12, 6, or 3 o'clock position, if possible.

Providing protection for an executive does not happen by chance. It is based on a structured and effective approach using *comprehensive protection formations*. Positioning security around and near an executive is not enough and will require the use of strategic protection security formations. The executive protection professional should remain close (arm's reach) to the executive at all times; because the overall objective is to protect the executive from harm and/or embarrassment.

The following formations are used in close-protection security today and have proven to be an effective and resilient tool in the overall security plan. ***Lone formation*** utilizes one security person (executive protection professional) with the executive and can be used in both internal and external movements. The lone formation requires the executive protection professional to stand behind the executive at an angle and not directly behind for better *field of view and observation*.

Secondly, the executive protection professional must maintain an ***arm's reach*** from the executive at all times in the event of an attack. It is important that the executive protection professional remain vigilant and maintain the "arms reach" behind the executive (Dale 2008; Oatman 2006). Some close-protection professionals argue that the executive protection professional should not use their strong arm when executing a cover and evacuate method. Instead, the executive protection professional needs to have the strongest arm ready to retrieve a firearm. In my 30 years of experience, both in the public and private sectors, reaching for a firearm during an attack is a last resort, not to mention that most executives, and corporations in general, have a "no weapon" policy for all staff, including executive security personnel.

A third formation utilized is known as the ***slash or sweep formation***, which requires an *advance person* to lead the protective formation (which is mentioned in the *site advance* section). This formation requires a two-person security team; one as the *advance*, who knows exactly where the team must go, and the *number-one* who is responsible for the safety and security of the executive. Human nature will play a role in how the protective formation is effective when dealing with an attack. Instinct and human reaction many times causes individuals to engage an attacker when their responsibility may have been to the executive. This has occurred and will continue to happen; however, as long as an executive protection professional member within the security detail covers and evacuates the executive, the risk and danger levels are significantly reduced.

A fourth formation is known as the ***wedge formation*****,** which will require three protection security personnel and should be used when a higher threat level has been assessed on the executive. The use of an *advance* person, a *number one* behind the executive and another executive protection professional positioned either to the right or left of the executive can enhance the overall security environment for the executive. This formation is used in public settings where access by the public is possible. Most executives do not use this type of formation for many personal and financial reasons.

Close-Protection Motorcade Security

Motorcade and route management is a primary security mechanism for the executive security plan. Ensuring that the executive and the executive protection professional are safe while being transported will require strategic planning and critical thinking that anticipates danger and other risk concerns. Motorcade sizes may vary, but the fundamentals remain the same (Dale 2008; West 2018). Vehicle transportation is considered vulnerable, because the executive protection professional is not in a *strategic and ready position*. Individuals attempting to kidnap or harm the executive can easily approach and attack the motorcade. Motorcade planning must ensure that the executive protection professional is trained in evasive driving techniques. The executive protection professional driver must operate the vehicle in a safe and responsible manner at all times; and only when under attack should the operator make any evasive moves. The executive should be situated in the right rear of the vehicle to help position the executive for an on-side location arrival.

The executive protection professional must develop *secured routes* when transporting the executive in the motorcade. The first designated route is known as the ***primary route***, followed by a ***secondary route*** and in certain circumstances a ***tertiary route*** may be developed. Multiple routes are needed in the event of an attack, hostile surveillance, or just a traffic condition. The executive protection professional should observe all road and environmental conditions, as well as traffic laws on a particular route. Motorcade route challenges include construction, traffic congestion, demonstrations, roadway chock points, civil unrest, time of day, inclement weather, and pavement condition. The routes should be determined based on safety, but also the ability to evacuate and retreat in the event of an attack. Safe locations or *safe havens* along the route include police stations, fire stations, hospitals, government buildings, and even corporate offices.

The positioning of the motorcade vehicles is critically important and part of a strategic design platform in close-protection security. The theory of aligning cars is part of a security strategy that does not expose the executive unnecessarily and provides tactical positioning for the executive protection professional. After the vehicles have been inspected (checked for improvised explosive devices and mechanical problems), the vehicles are now ready for alignment and positioning. A motorcade configuration should include a *lead car* to pilot the motorcade. The lead car will know the motorcade routes and act as an advance towards identifying hostile surveillance or a dangerous condition that may affect the motorcade's movement (Dale 2008; West 2018). The second vehicle in the alignment usually referred to as the *limo* will transport the executive; and the third vehicle in the motorcade is known as the *follow vehicle;* which will have additional security personnel, if needed.

Known in the field as the *secured package, the* vehicles should be the same make, model, and color so the executive protection professional can rearrange the vehicles when needed to confuse an attacker as to which vehicle the executive may be positioned in. The positioning of the motorcade with the limo in the center also allows the follow-vehicle to become a replacement vehicle for the executive in the event that the limo was to become disabled. Routes for the executive when walking should be with the *flow of traffic* so the motorcade can proceed and continue to shadow the executive at a close distance.

Executive Protection: Residence Security

The executive protection professional will also be responsible for surveying and installing physical security and life safety systems at the executive's residence and/or place of business. Since many attacks, especially kidnapping, have occurred at a person's residence providing productive and effective security protection measures will be a necessary component of the overall executive protection security plan. Implementing physical barriers, such as fencing and motion sensor

lighting will protect the perimeter from a possible intruder. CCTV surveillance cameras should also be installed around the property with remote viewing capability for monitoring the cameras with a smart phone when away from the residence. Exterior protection should also include solid wood doors, ANSI-graded locking devices and anti-fragmentation window filming. Interior rooms of the residence should have intrusion detection sensors on windows and doors, glass break detection, and life safety equipment such as CO2 and smoke detection. Panic buttons must be stationed throughout the residence, i.e., front door area, kitchen, bedroom, gym, and other rooms deemed necessary in the event of attack, injury, or illness. Panic or safe room consideration should also be part of the security survey for rooms within the residence that could be used to shelter the executive.

Executive Protection: International Travel

The executive protection professional will have the responsibility for the security planning and risk analysis when traveling internationally. This can be both complex, as well as frustrating for the EPP because of foreign jurisdictions, culture, language, and international law. Globalization now requires executives to travel aboard to conduct business for the organization. The increased globe footprint requires a robust executive protection plan to increase security and reduce risk for the executive. Whether traveling locally or aboard, the executive protection professionals must apply a comprehensive site advance. However, global travel can be more complex and will require additional planning and logistics.

The executive protection professional should have an interpreter, which the local US Embassy in country can help find. The executive protection professional and the executive must understand the cultural and customs differences before entering the country. Additional concerns include health and medical services for the executive. Having personal experience protecting executives in a developing country, it is a challenge and will test the executive protection professional's ability and knowledge. Protection strategies must consider threats from criminal groups, terrorists, and emotionally disturbed people (West 2018).

Many executives, even in the face of known threats and increased risk, continue to travel abroad. Various locations across the globe are plagued with civil unrest and crime. The risk level will change and the executive protection professional must evaluate all threats and apply security resources as needed. It is critical that the executive protection professional continue to monitor the political climate, as well as any contributing social circumstances within the region. The adoption of a static and inflexible security posture is indicative of poor planning and inexperience.

The USA has available support mechanisms in many regions of the world that can help the executive protection professional when traveling with and protecting an executive. The available resources include the US Department of State and the FBI, who are available to assist and can offer intelligence and threat information on a specific country, region, or specific location. There are also commercial intelligence services that can assist in developing and monitoring current threat and risk levels in a specific country or location. It is recommended that the executive protection professional embrace robust and effective security solutions and do not depend on luck or chance to ensure the safety of the executive.

Prior to the executive's arrival on foreign soil, a security and risk assessment should be made by the executive protection professional in order to calculate the potential for danger. The survey must include all areas that will be visited including official sites, lodging locations, public access locations, and the airport. Part of the assessment should include conferral with the Resident Security Officer (RSO) of the State Department at the US Embassy to inquire about current threat and risk levels within a country or the location you will be visiting (USDS 1997). Commercial third-party security companies are also available to provide security and logistical support for the executive protection professional and the executive when traveling to a foreign destination.

Close-Protection Attire, Appearance, and Equipment

The executive protection professional must wear appropriate attire that is conducive to the professional environment. Like training, professionalism, and attitude, having the proper equipment and presenting a professional look are important in the overall protection of the executive. Protection equipment will vary for the executive protection professional depending on the security environment. The executive protection professional should carry the necessary equipment that will help facilitate the roles and responsibilities. The following equipment is recommended:

- Communications:
  Radio with surveillance kit (earpiece),
  Radio holder (if needed)
  Cellular telephone. Smart phone technology is recommended
- Flashlight:
  Compact flashlight with fresh batteries
- Writing note pad
- Working black ink pen
- Firearm (if authorized) with belt holster and extra magazine clip. Carry permit and other identification for law enforcement purposes.

As a member of the security team, the executive protection professional is on the front lines, not only in regard to an attack, but in the public's eye. Personal appearance is as important as training and both need to be followed and practiced on a continuous basis. The executive protection professional should be groomed and neat. Hair should not be long; it should be combed; finger nails cleaned and have good hygiene.

The required equipment for an executive protection professional is as important as the attire. The executive protection professional should dress in business wear, usually black, dark blue, and grey single-breasted suits. The executive protection professional should also wear a working watch and limited jewelry (Oatman 2006). White shirts and light blue shirts are preferred and ties should match the suit color. Since the executive protection professional can be expected to stand for extended periods of time, *walking* dress shoes of good quality are recommended. Heavy over-coats are not recommended, but a trench coat is the preferred choice. Socks should be dark colored matching the suit or shoes being worn. In certain environments, suits are impractical, like a summer resort. The executive protection professional should have causal clothes in a travel bag at all times. Light weight slacks, like khakis are preferred, along with golf shirts with a collar.

Conclusion

Executive protection is both a challenging and demanding assignment. However, when applied correctly, the executive protection professional will enjoy this assignment for years to come. The ability to meet influential people, global travel, and the many life experiences working as an executive protection professional is worth the effort. The executive protection professional must identify the critical stakeholders when assigned to protecting a senior leader in an organization. The executive protection professional must also realize the differences in cultures within the many different industries, and that corporate cultures vary and are not alike. The executive protection professional should remain humble and learn the fundamentals of executive protection, as each day, a new lesson may be presented.

The executive protection professional should also be careful when working as an "independent contractor" for an organization because of the legal exposure and possibility of a civil suit if actions are taken by the executive protection professional against a person known, or deemed a threat, to the executive. The need for protecting a C-suite executive transcends many levels in a corporation and the executive protection professional must remember that each executive will exhibit a particular personality, level of tolerance, and willingness to follow a security plan. Time will help the executive protection professional better understand the executive's world, the relationship with the executive, and the ability to get the job done.

Definition

The primary purpose of the Federal Emergency Management Agency (FEMA) is to coordinate the response to disasters in the United States that overwhelm local and state authorities while also providing personnel and resources to protect and safeguard life and property, prior to and following disasters.

Introduction

FEMA was founded on April 1, 1979 when President Carter signed *Executive Order 12127* to address the growing need for an agency that primarily focused on helping Americans to deal with disasters. Specifically, FEMA's role is in "preparing for, preventing, mitigating the effects of, responding to, and recovering from all domestic disasters, whether natural or man-made, including acts of terror" in the United States (see History on FEMA). Since its official inception, FEMA has provided countless resources and conducted disaster relief efforts across the United States, both to prepare for and respond to disasters. FEMA is also the primary agency that oversees the National Flood Insurance Program (NFIP) and is the lead agency in providing aid (both monetary and resources) to communities and citizens affected by disasters. FEMA also handles administrative issues regarding natural disasters and facilitates cooperation between federal agencies, local governments, and affected citizens, when applicable. Table 1 shows the types of FEMA programs and a description of their tasks.

History

The origins of FEMA lie in the Congressional Act of 1803, which was passed to provide assistance

Federal Emergency Management Agency, Table 1 FEMA programs and their description of tasks (FEMA 2008)

Program Types	Description of Tasks
Service to Disaster Victims	1. Provides care for victims 2. Assists with multilingual and special need requirements
Integrated Preparedness	1. Works with partners, agencies, and governments to ensure security and preparedness 2. Aids with recovery from attacks, disasters, and emergencies
Operational Planning and Preparedness	1. Works with partner to assist jurisdictions to plan 2. Ensures plans will aid activities
Incident Management	1. Responds to hazards 24/7 2. Trains and certifies staff 3. Works with partners to improve and update standards
Disaster Logistics	1. Implements logistics and procurement systems for 1st responders to plan, identify, track, and distribute supplies 2. Works with partners, donors, and contractors to improve integration and support
Hazard Mitigation	1. Improves risk analysis and hazard mitigation planning to reduce physical and financial impact 2. Implements practices to improve safety and recovery and reduce financial burden
Emergency Communications	1. Works with federal, tribal, state, and local partners to ensure communications 2. Ensures integrated operational link 3. Advocates for disaster emergency communications for 1st responders
Public Disaster Communications	1. Coordinates hazards messaging using public risk, partnership management, and employee communication 2. Provides information for victims, partners, and stakeholders
Continuity Programs	1. Integrates public alert and warning system 2. Provides continuity of government operations and functions

to a New Hampshire town after devastation from a large fire (FEMA 2008). This Act is considered the first piece of legislation passed in the United States addressing disasters and was instrumental in helping legislators recognize the need for disaster legislation. During the following century, ad hoc legislation was passed more than 100 times in response to hurricanes, earthquakes, floods, and other natural disasters (FEMA 2018). Laws unique to each disaster authorized financial assistance to victims and provided both personnel and equipment to assist in recovery and clean up.

In the mid-1930s, as the population increased, more people were being affected by natural disasters. Disaster assistance and recovery became a popular concern among lawmakers and citizens, leading to the Reconstruction Finance Corporation authorizing disaster grants to those affected by disasters (FEMA 2018). Several developments occurred as a result, including the Bureau of Public Roads was able to repair damage to infrastructure (e.g., highways, bridges), the Flood Control Act of 1965 provided projects to build flood control mechanisms, flood insurance was made available for homeowners, and presidents were able to declare disasters (FEMA 2018). However, the financial burden and logistic impact of obtaining help from a variety of agencies during natural disasters led to an increasing need for an efficient and centralized agency to help prepare and recover from disasters so FEMA was created (FEMA 2018).

In 2003, FEMA was integrated into the United States Department of Homeland Security (DHS). (FEMA 2008, 2018; see DHS and DHS Act of 2002 in this encyclopedia). DHS is a cabinet-level department, comprised of 23 separate agencies that allows the government to have a coordinated response to disasters and emergencies affecting national security (see New Mission on FEMA.gov). This restructuring aimed to centralize communication, solve inconsistencies, and secure resources and personnel for FEMA to utilize in major disasters (FEMA 2018; see Emergency Management: Crisis Management and Response; Emergency Management: Emergency Alert

Systems; Emergency Management: Evacuations; Emergency Management: Incident Command System; Emergency Management: National; Human made Disasters; and Natural Hazards in this encyclopedia).

FEMA Costs

Evaluation of FEMA's performance in recent years has resulted in mixed reviews, particularly in light of its costs (DHS 2018). Annual expenditures for FEMA fluctuate depending on the occurrence of disasters (e.g., see DHS 2018). The government was only minimally involved, other than providing US military to help communities following disasters. However, spending has increased in recent decades as a result of both size and frequency increase in federal aid packages as needed by states experiencing often multiple disasters (e.g., California for damage from earthquakes, landslides, and wildfires). According to Edwards (2014): "Annual average FEMA spending was $0.7 billion in the 1980s, $2.8 billion in the 1990s, $13 billion in the 2000s, an $13 billion so far in the 2010s (para 9)." He reported that: "Since 2000, 61 percent of FEMA spending has been for disaster relief, with 20 percent for ongoing preparedness grants to state and local governments, and 12 percent to the National Flood Insurance Program. The remaining 7 percent has been allocated to other programs and administrative costs" (para 10).

Conclusion: The Future of FEMA

While the tasks of FEMA change with every disaster, the new FEMA Strategic Plan is setting the direction for the future and education is an overarching theme of the agency (DHS 2018). In recent years, FEMA officials have implemented two key changes (DHS 2018). First, they have shifted the narrative regarding disaster preparedness, response, and emergency management from a reactive to a proactive approach (see ▶ "Emergency Management: Preparedness and Planning", ▶ "Emergency Management: Recovery", and ▶ "Emergency Management: Incident Command System" in this encyclopedia). Second, they have a heightened focus on educating citizens, first responders, and local officials on disaster preparedness at the community level through the Center for Domestic Preparedness, instead of relying on the government and its agencies to respond following a disaster. FEMA provides online training through its Emergency Management Institute and National Training and Education Division, as well as onsite all hazards training at its Center for Domestic Preparedness (see ▶ "HAZMAT" in this encyclopedia). Congress requires that DHS provide budget overviews for FEMA spending (e.g., DHS 2018). However, there is a need for critical evaluation of federal disaster actions that would allow the government to determine which activities contributed to success and which were inefficient, counterproductive, and a waste of money.

Fire: Evacuation (Engineer Solutions)

Joshua Reichert
Fire Protection and Paramedicine Sciences, Eastern Kentucky University, Richmond, KY, USA

Keywords
Fire protection · Life safety · Egress

Definition

Evacuation, when referring to fire protection and life safety, is the action or notifying and egressing people from a possible hazardous area to a safe location.

Introduction

An efficient evacuation during any emergency event is key to life safety. In order to achieve an efficient evacuation, correct components need to be in place. This includes having a correctly defined evacuation strategy, which is dependent on the scenario, type of building, and occupants involved. This also involves having the correct fire protection devices to detect and notify occupants in a timely manner. Managerial functions must also be taken in to consideration to conduct fire drills and life safety checks to ensure the functionality of the evacuation process.

Evacuation Strategies

To effectively evacuate any building, consideration must be given to the type of building and the occupants in order to determine the best suited evacuation strategy. The most common evacuation strategies include delayed evacuation, phased evacuation, partial or zoned evacuation, total evacuation, and no evacuation (O'Connor and Cohn 2008).

Delayed Evacuation

In cases where a building has occupants with disabilities, there may be a need to provide a safe place for these occupants to evacuate to until they can be assisted to safety. This area is known as an area of refuge and is to be constructed as to protect people from the hazards of fire. NFPA 101 further discusses the requirements of an area of refuge (NFPA 2018). Occupants with disabilities are notified in a similar manner to everyone else that an evacuation is needed, but because they are not able to safely evacuate alone, they evacuate to the area of refuge to await emergency personnel to assist their evacuation.

Phased Evacuation

A phased evacuation strategy, commonly used in high-rise buildings, is used to evacuate those occupying floors closest to the fire first, followed by the rest of the occupants in the building. This

strategy is utilized based on the assumption the fire will not spread too quickly as to affect those waiting for the initial floors to evacuate. This strategy also ensures emergency stairways do not become too densely populated such that the occupants on the fire floor – the ones at the highest risk for exposure to the fire – cannot safely enter the protected stairwell (Tubbs and Meacham 2007).

Partial or Zoned Evacuation

Partial or zoned evacuation relies heavily on passive and active fire protection features. This strategy is best utilized when the evacuation of all occupants requires a tremendous effort and cannot be completed in a timely manner. Hospitals and nursing homes are common places to see a partial or zoned evacuation. For this strategy, only the zone where the fire has been detected is activated, the remainder of the people shelter-in-place (see below). The fire and hazards from the fire are contained in this zone by the use any combination of fire walls, fire barriers, sprinklers, etc. (Tubbs and Meacham 2007, 2008).

Total Evacuation

The most common evacuation strategy is total evacuation. That is, after a fire is detected, everyone is notified, and everyone in the building is evacuated at one time. This is the best strategy in terms of evacuating everyone safely from a building in a timely fashion, but considerations must be given if one of the previously mentioned strategies need to be deployed based on the building and occupant characteristics (Tubbs and Meacham 2007).

No Evacuation (Shelter-in-Place)

In some cases, the best evacuation strategy can be to not evacuate at all. This strategy may also be referred to as protect-in-place, defend-in-place, or shelter-in-place. The idea behind this strategy is to provide an adequate combination of passive and active fire protection features to allow occupants to safely remain in an area. This strategy is common for buildings in which occupants have a difficult time self-relocating. Adequate training of personnel may be required to ensure appropriate actions are taken, such as closing doors to prevent fire and smoke spread (Tubbs and Meacham 2007).

Evacuation Process

During an emergency event, a timely evacuation needs to occur in order to protect lives. When a fire occurs in a structure, the environment is continually being changed by that fire. Temperatures are increasing, visibility is being reduced, toxic chemicals such as carbon monoxide are being released from the fire, structural members are being weakened, etc. At some point, these variables changing the environment will have a limit in which humans can be exposed to before becoming incapacitated and unable to evacuate themselves. These limits that humans can be exposed to before becoming incapacitated are known as tenability limits.

The time between when a fire occurs and when a tenability limit has been reached is known as the Available Safety Evacuation Time (ASET). This would be the amount of time a person has to be notified of a fire event and evacuate before they would become incapacitated and unable to self-evacuate. This time can be determined by an engineering analysis through the use of means such as hand calculations and/or computer fire modeling.

Once the ASET is known, a time scale in which to accurately evacuate people is known. The Required Safety Evacuation Time (RSET) is the amount of time between when a fire occurs and when an occupant reaches a safe location. In order to prevent the loss of lives, the RSET must be lower than the ASET.

RSET is commonly divided into four different variables to calculate. This includes the summation of the time between when a fire ignites and when a fire is detected (time to detection), the time between a fire being detected and the occupants being notified (time to notification), the time between when an occupant is notified and when the occupants begins to egress (premovement time), and the time it takes a person to egress from their starting position to a safe location (movement time).

Time to Detection (t_d)

The time it takes for a fire to be detected will heavily depend on the characteristics of the fire and the detecting method.

Fire Characteristics

Many different variables define the characteristics of a fire and their importance for detecting a fire. The first variable to consider is the growth rate of the fire. Fires are primarily defined by their heat release rate or the rate in which a fire releases energy. As the burning area of a fire grows, the heat release rate typically does too; this is the growth of this fire. Fires with slow growth rates will cause delays in certain types of detection methods.

Coupled with the growth rate of the fire, the soot yield of different types of fuels will influence the detection time. For detectors that activate from an obscuration means require a higher soot yield to reach this obscuration activation threshold, so a fire with a low soot yield will be less effective and cause a longer time to detection for obscuration detectors. Cleaner burning fuels with lower soot yields may require other detection means such as heat detection or air sampling detection.

Detecting Methods

The detecting method will also have a significant impact on how long until a fire is detected. The fastest method of detection will be if the correct detector is selected for the correct scenario. However, it is possible that fire detectors are selected for the wrong possible fire scenario or are not well maintained and do not activate as quickly as they should. The most typical, and quickest, type of detection when properly used and maintained are (NFPA 2019b):

- Ionization smoke detection
- Photoelectric smoke detection
- Combination ionization and photoelectric smoke detection
- Heat detection
- Air sampling detection

Sprinkler systems can also be utilized as a detecting method. Sprinkler systems are required to utilize notification devices, such as water motor gongs or connection to the fire alarm panel to notify occupants. This type of detection will generally be slower than smoke detection devices as sprinkler heads will have activation temperatures that will take longer to reach than the thresholds of smoke detection devices (NFPA 2019a).

Another consideration is scenarios without smoke detectors. In this case, the time to detection relies on the fires to be detected by humans. This involves humans waiting for cues such as visibly seeing smoke, visibly seeing flames, smelling smoke, feeling temperature increases, etc. This is commonly seen in residential homes within smoke detectors, as the fire is allowed to grow unnoticed for a significant amount of time before occupants are made aware of the fire.

Time to Notification (t_n)

Once a fire has been detected by one of the previously mentioned means, the next step is to notify the occupants. The ability to notify occupants will also be heavily reliant on the type of devices present. A fire alarm system required to follow NFPA 72 will require the system to activate all notification devices within 10 s of detection (NFPA 2019b). Notification devices consist of audible notification, visual notification, or other stimuli.

Audible Notification

Two types of audible notification are common; coded notification devices and voice notification devices. A coded notification device sounds in a coded sequence to notify occupants. It is important of anyone that hears a coded fire alarm to quickly interpret it as such, for this reason, in 1996, the American National Standards Institute (ANSI) and the National Fire Protection Association (NFPA) recommended a uniform coded signal known as the temporal-three (T-3) alarm pattern. The T-3 was required for all new construction following this time as required by the 1996 edition of NFPA 72 (NFPA 1996).

Voice notification devices have become increasingly common in fire protection designs.

A voice notification can be a prerecorded message used to inform occupant to evacuate in the case of emergencies. Studies have shown that a voice alarm is more effective than the T-3 alarm due to the fact the voice notification is less ambiguous and hence leads to less misinterpretation when occupants hear the alarm (Nilsson and Johansson 2009; Proulx 1995). Other studies have shown people cannot accurately identify the sound of a T-3 alarm resulting in a low sense of urgency (Proulx and Laroche 2003).

Audible notification selection is important when it comes to waking children. Many studies have shown the T-3 alarm signal is minimally effective at waking children under the age of 10 years (Bruck 1998; Bruck et al. 2004; Thomas and Bruck 2010). In contrast, voice alarms, such as those using the mother's voice, have been demonstrated to be more effective than tone alarms in waking and rousing children to escape (Bruck et al. 2004; Smith et al. 2006, 2018).

Visual Devices

Visual notification devices such as strobe lights are utilized when ambient sound conditions are not conducive for audible notification or if occupants have a hearing impairment. The use of visual notification devices is required by NFPA 72 (NFPA 2019b).

Other Stimuli

There are plenty of other cues that may be available to occupants to notify them of a fire event. These are the same cues previously mentioned in time to detection, in which occupants receive cues directly from the fire itself. In these cases, the time to detection may be long; however, the notification should be short for the person seeing flames or smoke; however, if this person needs to notify others directly, the notification for these occupants may be significant. A similar scenario occurred in the Winecoff Hotel in Atlanta, GA, in 1946. This building did not have a detection and/or notification system, and when the fire was detected, the night manager attempted to phone rooms to warn the occupants of the fire. Hundred and nineteen lives were lost and 90 injured as a result of this hotel fire (McElroy 1947).

Premovement Time (t_p)

After an occupant has been notified and is aware, an evacuation is needed; this occupant has entered the premovement time. The premovement time is any time between when the occupant is notified and when the occupant begins to egress to an exit. The premovement time is the most difficult to predict in evacuation because of the many human behavior factors present. During this time social influences, environmental influences, and cognitive influences may all influence the decision when to evacuate. Document premovement times have been recorded from experiments and real fire event (Fahy and Proulx 2001).

Social Influences

Many social factors can influence people when they are notified of a fire event. The first of which is whether or not the person is alone or not. When a person is surrounded by other people and a fire alarm sounds, occupants are likely to look at each other for cues on whether or not to evacuate (Nilsson and Johansson 2009). This social influence can be linked to people not wanting to be different than the crowd.

Another social factor is whether or not loved ones are present. If an occupant is in a department store and a fire alarm sounds, occupants are likely to seek out those they came to the store with (Shields and Boyce 2000). We see a similar social factor in private residences where mothers will seek out children before they evacuate themselves (Canter et al. 1980).

Environmental Influences

The environment someone is in when notified to evacuate can help determine how quickly the evacuation begins. One comparison that can be made is a person in a public building versus in a house. Homeowners will feel a greater sense of ownership and are more likely to fight the fire to protect the structure than to evacuate it. Renters in a public building are less likely to have of a sense of ownership to the building and will begin to evacuate sooner.

Another environmental factor that influences people before they evacuate can also be seen in the example of homeowners versus renters in the

number of personal belongings. It has been seen that homeowners are more likely than renters to stop to collect their personal belongings before evacuation begins (D'Orazio and Bernardini 2014).

Cognitive Influences

Cognitive factors influence how someone perceives and makes decisions based on previous knowledge and experiences. When a person is notified of a fire event and is aware an evacuation is needed, that person will begin drawing on personal experiences to determine what to do next. People that have experience with fire will have different experiences to draw upon and will act differently than people that do not have those experiences. One cognitive ability people are not well equipped with, which may slow evacuation time, is their ability to predict the growth of fire (Fridolf and Nilsson 2011). In the current social media age, it is not uncommon to see people posting pictures or videos online of a fire instead of evacuating. Part of this reason is due to their inability to accurately predict the fire growth and as a result they delay their evacuation.

Movement Time (t_m)

After an occupant has decided to egress to a safe location and exits to this safe location, this is considered movement time. Movement time takes a few variables in to consideration such as the route an occupant is going to take and the speed in which the person can travel. Once the route is determined (or the distance to the exit), it can be used with the movement speed (distance per time) to determine the movement time.

$$\text{Movement time (minutes)} = \frac{\text{Distance (feet)}}{\text{Speed (feet/minutes)}}$$

Egress Route

When a person begins to evacuate, the same factors as premovement time can influence the route taken. Social influence may influence a person into taking the same route as everyone else, environmental influence may cause someone to be unfamiliar with a building and use the only exit they know (the one they came in), and cognitive influences may allow them to override the other two influences based on their previous experiences and knowledge.

Studies have shown, when people are unfamiliar with a building, most people will utilize the most familiar door, which is usually the primary entrance/exit (Nilsson et al. 2008). This can cause an overcrowding situation along an egress route and increase the overall movement time. Directional signage, along with a voice alarm, has been shown to help prevent this mentality by people evacuating (Galea et al. 2017). Once the route has been selected by the occupant, the overall distance to a safe location can be determined.

Movement Speed

The speed an individual can walk is a function of the density of the area. When a person can walk unimpeded with no one around them on a flat surface, they can walk with full strides, and this average speed is typically around 235 ft./min (1.19 m/s) (Fahy 2008). When a person is moving up and down stairs or through doorways, density will also be a large factor. For this purpose, it is also important to determine the flow (persons/s) and specific flow (persons/min/ft. of effective width) of these locations based on the density. These locations will be slower than previously mentioned and can be considered limiting factors in the movement time calculation. Section 4 Chap. 2 of the *Fire Protection Handbook* provides a full text on calculating egress times (Fahy 2008).

Conclusion

Many factors influence an efficient evacuation. During the initial stages of a building design, consideration should be given to the characteristics of the people that will occupy the building and what characteristics the building itself will have. A full analysis should be conducted using this information to determine the best evacuation strategy to utilize. An engineering analysis can also be conducted through the use of hand calculations and/or computer models to determine if the evacuation strategy and fire protection features utilized

are adequate to provide efficient life safety to the occupants. Engineers can design a building and the egress route as a prescriptive design in which all national and local fire codes are utilized; however, a full engineering analysis to create a performance-based design can be utilized for more unique buildings to show an adequate level of life safety to the occupants achievable through other strategies than what is recommended by code.

Definition

Best practices in the field of fire engineering are procedures that are accepted or prescribed as being correct or most effective.

Strategies for fire engineering is a plan of action designed to achieve an overall aim, usually life safety and property conservation.

Introduction

When architects and engineers collaborate on a new building, extension to an existing building, or renovation to a new building, fire and life safety is always a consideration. A specialty in the fire community that exists to assist with that is fire protection engineers. Fire protection engineering is a professional licensure governed by the state in which the person would like to be licensed in. To become a licensed professional engineer (PE), a person would need to complete a 4-year degree in engineering from an accredited engineering program, pass the Fundamental of Engineering (FE) exam, complete a state-determined number of years working under a licensed PE, and then pass the Principles and Practice of Engineering (PE) exam.

When designing fire protection and life safety for a building, engineers have two best practices in which to choose from: prescriptive design and performance-based design.

Prescriptive design is the design of fire protection features using codes and standards that have been developed for generic buildings. This could include codes and standards from organizations such as the International Code Council (ICC), National Fire Protection Association (NFPA), state and local codes and ordinances, state or local amendments to national codes such as ICC and NFPA, or even corporate codes and standards for fire protection.

The other best practice to design a building with fire protection features is a performance-based design (PBD). Utilizing PBD includes designing the fire protection features specifically for the performance and the functions of the building. To provided a level of safety that is equivalent or exceeds what would be provided using prescriptive design, PBD utilized engineering analysis.

Prescriptive Design

Prescriptive fire protection design is the practice of designing fire protection features per accepted and approved codes and standards. A prescriptive-based code or standard prescribes fire safety for generic use of application. Building codes have a long history in mankind as it has been recognized that responsibility needs to be put on to a building to ensure a level of safety to a building owner. The earliest building code is believed to been written between 1955 B.C. and 1913 B.C. under King Hammurabi of Babylon. Once such building code written stated, “If a house fell and killed the owner of his child, then the building, or his child, would be slain in retaliation” (Foliente 2000).

King Hammurabi identified that buildings should be responsible for the quality of product being handed over to a person that many have no

knowledge of buildings. While mankind has developed and punishments are less extreme, building codes have also developed. Within the United States, different codes and standards exist for use in prescriptive design. While the codes outline a set of rules that knowledgeable people recommend for others to follow. This is not law but can be adopted into law. A standard is the more detailed elaboration of how to meet the code. More specifically, a code tells you what needs to be done and a standard tells you how to do it. These codes and standards help a fire protection engineer develop a prescriptive strategy for designing fire protection.

The ICC was established in 1994 as a nonprofit organization dedicated to developing a single set of comprehensive and coordinated national model construction codes. The formation of the ICC was due to three separate nonprofit organizations which were developing separate sets of model codes to be used in the United States. The three separate organizations were the Building Officials and Code Administrator International, Inc. (BOCA), International Conference of Building Officials (ICBO), and Southern Building Code Congress International, Inc. (SBCCI). It was recognized one single organization was needed without regional limitation; hence the formation of the ICC was made a realization (ICC).

Currently, the ICC produced 15 different codes covering different concentrations. Pertaining to fire protection design, the most important codes published by the ICC are the International Building Code (IBC), the International Fire Code (IFC), the International Plumbing Code (IPC), and the International Residential Code (IRC) (ICC n.d.).

International Building Code – This code is the foundation for all codes from the ICC. It has been accepted by most jurisdictions within the United States as well as some jurisdictions internationally.

International Fire Code – This code is designed to meet the needs to address conditions hazardous to life and property from fire, explosion, handling or use of hazardous materials and the use and occupancy of buildings and premises. This code establishes minimum regulations for fire prevention and fire protection systems using both prescriptive and performance-related provisions.

International Plumbing Code – This code sets minimum regulations for plumbing systems and components to protect life, health, and safety of buildings' occupants and the public. The IPC covers a range of topics such as backflow prevention, fixtures and fittings, water supply and distribution, etc. These covered topics are important when designing sprinkler systems for a building.

International Residential Code – This code is designed to address one- and two-family dwellings and townhouses of not more than three stories above grade. The IRC covers aspects of construction such as building, plumbing, mechanical, fuel gas, and electrical, which all play a role in fire prevention and fire protection of residential structures.

The National Fire Protection Association (NFPA) is also another organization that creates and publishes prescriptive codes, standards, and recommended practices. NFPA was formed in 1896 and has been devoted to eliminate death, injury, and property and economic loss due to fire and electrical and related hazards. NFPA, as of 2018, delivers information and knowledge through more than 300 consensus codes and standards, research, training, education, outreach, and advocacy. Each code and standard through NFPA are revised and updated every 3–5 years and normally take about 2 years to complete (NFPA n.d.).

Jurisdictions, both state and local, regulating building design and fire protection must adopt codes in order to become law. Jurisdictions may also determine the codes are not strict enough in certain areas and opt to either not adopt the national codes, but to write their own to enforce. Jurisdictions may also decide to adopt the national codes but to write amendments to certain parts of the code. For example, the state of Georgia adopts ICC codes such as the IBC and IFC but have amendments to certain sections of the codes (Georgia Department of Community Affairs n.d.).

Performance-Based Design

Performance-based design (PBD) is the second practice that an engineer may use to design fire protection features for a building or process. The Society of Fire Protection Engineers (SFPE) has developed a strategy for performing a performance-based design for fire protection titled, *SFPE Engineering Guide to Performance-Based Fire Protection* (SFPE 2007).

SFPE was established in 1950 and incorporated as an independent organization in 1971. As of 2018, the society has over 4600 members and 92 chapters, including 17 student chapters worldwide. It is the mission of SFPE to "define, develop, and advance the use of engineering best practices; expanding the scientific and technical knowledge base; and educate the global fire safety community, to reduce fire risk" (SFPE n.d.).

In the guide, SFPE has developed a step-by-step guide to conducting a performance-based design.

Step 1: Define Project Scope

Defining the scope of a project should always be the first step in any design project. Without a well-defined scope, it is possible to not fully understand how to accomplish this project and cause errors that could cost money at later stages in the design process. Some of the information needed when defining the scope includes the constraints on the design and the project schedule, building construction and features desired, occupant characteristics, building characteristics, and applicable codes and regulations.

Step 2: Identify Goals

Once the objectives of the project are understood, it is easier to define the goals of the project. This should always include the levels of protection for people and property. Other considerations for a goal could be preservation of historical buildings or items, business continuity, and protection of the environment.

Step 3: Define Objectives

The objectives of the design project are the design goals with tangible values for evaluation purposes. This could include dollar value loss, loss of life, or any other impacts from a fire event.

Step 4: Develop Performance Criteria

This step includes developing the performance criteria that the design will be expected to meet. This is a further refinement of the design objectives and will include items such as tenability limits for life safety. The tenability limits will need to be well-defined and agree upon between all authorities and engineers to continue forward with the project.

Step 5: Develop Design Fire Scenarios

This step could include extensive research and a good understanding of the function of the building in which the fire protection features are being design for. By taking the building type and function into consideration, fire scenarios can be derived. This could include expected fuel packages, locations, peak heat release rates, growth rates, and products of combustion. An adequate amount of fire scenarios should be selected to ensure all possible worst-case scenarios have been tested again the fire protection design.

Step 6: Develop Trial Designs

This step is where the actual fire protection features are introduced. Consideration should be given to what the stakeholders and building owners would like within the building. This could include proposed fire protection systems, construction features, and operations. At this step in the design process, an engineering and all approving parties should determine and agree how the evaluation of each fire scenario to each trial design is going to occur. Typical evaluation techniques include hand calculation and computer fire modeling.

Fire protection hand calculations are widely known and used within the fire protection community. While hand calculations are quick and time-efficient, most are empirical correlations and have limitations. Hand calculations are also good for small-scale applications and become too difficult and tedious for large-scale buildings for a performance-based design.

Computer fire modeling has become revenant in the fire protection community for performance-based design. Computer fire models are usually divided into two categories, two-zone models and field models.

Two-zone models divide a computational domain into two zones, typically upper and lower layer within a compartment. Two-zone models have a low computational demand and can be more efficient on small scales but still have limitations. An example of a two-zone model is the Consolidated Model of Fire and Smoke Transport (CFAST), which is a free computer fire model maintained by the National Institute of Standards and Technology (NIST) (NIST n.d.-a).

Field models, also known as computational fluid dynamic (CFD) models, divide the computation into a user-specified number of zones. This allows for adjustments to the number of calculation zones; however, with an increased number of zones comes an increase in computational demand. Many field models exist in industry; one such is named Fire Dynamics Simulator (FDS) and is a free computer fire model maintained by the NIST (NIST n.d.-b).

Step 7: Evaluate Trial Designs

The next step in the design project is testing the chosen fire scenarios against the trial fire protection designs utilizing the chosen evaluation technique. The evaluation technique should provide analytical data that can be used to compare to the performance criteria.

Step 8: Determine if Design Meets Performance Criteria

Any trial fire protection designs that fail to meet the performance criteria for any of the fire scenarios can either be altered to change or increase fire protection features, or other means of fire protection must be considered. If any of the trial fire designs pass the performance criteria for all of the fire scenarios, this design can be deemed adequate to meet all the objectives of the project. However, it is likely none of the trial fire protection designs pass the performance criteria for fire scenarios, and this could be caused by restricting objectives, goals, or performance objectives, too severe of fire scenarios, or even incorrect use of the evaluation method. If no trial fire protection designs pass the performance criteria for all the fire scenarios, these possible restrictions may need to be readdressed, and the process starts over.

Step 9: Select the Final Design and Report

If there are more than one trial fire protection designs that pass the performance criteria for all fire scenarios, then one trial design will need to be selected. With more than one option, this allows the building owner to determine which design best fits their monetary and design needs. All steps of this performance-based design should be documented in a final report. This final report should be approved by additional engineers, authority having jurisdiction (AHJ), and all stakeholders.

Conclusion

Fire protection design is a field in which is very dynamic. New fire hazards and new building designs are always going to keep this field from remaining static. Fire protection professionals have a few best practices and strategies to achieve adequate fire protection to provide life safety for occupants. The use of national and local building and fire codes provide a generic best practice and strategies to design the fire protection features. If buildings do not fit the mold of the generic codes, it may be more beneficial, or needed, for a fire protection professional to conduct a performance-based design. In order to do so, the fire protection industry has stabled some best practice and strategies in a step-by-step guide to insure success when conducting this type of design. Either strategy should ensure the objectives of the codes and standards are met to ensure things such as life safety, building protection, and environmental protection.

Keywords
Fire mitigation

Definition

Fire protection is the methods and actions to reduce and mitigate the effects and damage caused by a fire event.

Fire prevention is the methods and actions taken to reduce the likelihood of a fire event.

Life safety is the primary goal in fire protection utilizing a method or system to protect the life of occupants.

Introduction

The United States and mankind in general have always had a fire problem. What was and has always been one of the most important tools to the human race can quickly become one of the deadliest. Humans learned to harness fire for many uses such as to cook food and stay warm. But just as fire has good applications, it has its bad sides as it burns down buildings and cities, destroys forests, and takes lives when out of control.

Fire protection has been seen as early as 300 B.C. by the Romans as a slave fire department. By A.D. 26 a full-time fire department in Rome was flourishing and was charged with enforcing fire prevention safeguards and punishing any person that did not follow the safeguards or was responsible for a fire event (Robertson 2005).

Many attempts to mitigate the impact of fires have also been seen throughout time. The Great London Fire of 1666 destroyed approximately 13,200 houses, 87 churches, and 50 livery halls over an area of 436 acres (Cote 2004). The primary construction material in London at the time was wood and straw. However, this fire enforced a need to prevent the spread of fire from one building to another, which lead to the way London looks today, with majority of construction being brick and stone.

Today, fire protection is the application of fire prevention and fire mitigation to provide life safety, property conservation, and environmental protection. The fire protection field consists of, but is not limited to, fire fighters, fire

marshals, fire prevention officers, fire protection engineers, fire protection specialists, fire investigators, etc. The best ways to achieve adequate fire protection are to provide fire prevention and, if a fire does occur, mitigate the impact of the fire as much as possible. Many best practices and strategies are incorporated into providing adequate fire prevention and fire mitigation.

Fire Prevention

Fire prevention has many levels associated with it. Prevention starts before products are even released to distributors or retailers by testing regulated by government agencies. However, not all fire events can be prevented, and for that reason, fire education is provided as a secondary fire prevention method.

Consumer Product Fire Prevention

In recognition of the fact that manufacturers and distributors should not be allowed to release products to a consumer without consideration to the safety of the product, laws such as the Consumer Product Safety Act (CPSA), Flammable Fabrics Act (FFA), etc. were enacted to give regulatory power to the Consumer Product Safety Commission (CPSC).

The CPSC is an independent federal regulatory agency formed in 1972. It is the mission of the CPSC to protect the public against unreasonable risks of injury or death from consumer products through education, safety standards activities regulations, and enforcement. The CPSC is committed to protecting consumers and families from products that pose a fire, electrical, chemical, or mechanical hazard (United States Consumer Product Safety Commission n.d.).

In order to educate the public and consumers of potential harm or ensure consumers of safety products, the CPSC releases technical reports. These reports are not always written and published by the CPSC as they may release technical reports conducted by other entities within the government, such as the National Institute of Standards and Technology (NIST). Further education is provided by the CPSC in the form of Residential Fire Loss Estimates. This provides the public such as consumers, manufacturers, distributors, and even fire departments with the ability to identify fire trends and allow the public to adjust accordingly.

The CPSC enforces consumer product safety under given laws/acts regulating different products or substances utilizing federal regulations. These regulations are named the Code of Federal Regulations (CFR). The CFR is published by the Federal Register by the executive department and agencies of the federal government of the United States. The CFR is divided into 50 titles covering a broad range of subjects. Both fire prevention and fire protection areas can be found located in different Titles of the CFR.

Fire Prevention Programs

Despite federal regulations, fires still occur in all types of locations with potential for harm. The next line of defense to prevent these fires are fire prevention programs. One of the most recognizable and longest lasting fire prevention program is that of Smokey Bear.

In 1944, the US Forest Service and the Ad Council agreed that a fictional bear would be the symbol for their joint effort to promote forest fire prevention. By 1947, and to this day, Smokey Bear's slogan, "Only YOU Can Prevent Forest Fires!" is still widely known (Office of Communication 2014).

Other national organizations also provide fire prevention programs. Every year in October, the nation recognizes Fire Prevention Week and is considered the longest running public health observance. Fire Prevention Week was first enacted in 1925 by President Calvin Coolidge in commemoration of the Great Chicago Fire of 1871. The National Fire Protection Association (NFPA) has been the official sponsor of Fire Prevention Week since its enactment. Every year, NFPA promotes a different fire prevention theme to the public (NFPA n.d.).

Local fire departments, paid, volunteer, and combination, are all known to provide fire prevention programs to their community. Many fire departments around the country have a Fire Prevention Officer charged with such programs. It is

possible for fire departments to use both local and national statistics to determine trouble areas to focus on for fire prevention or for fire departments to focus on the highest risk demographic of their community. It is common for fire departments to offer fire prevention demonstrations for the community and programs for younger children. Fire departments also have authority to conduct facility inspections to ensure code compliance, which is also a form of fire prevention.

Employers are also in charge of providing a workplace safe from recognizable fire hazards. The Occupational Safety & Health Administration (OSHA) was created in 1970 when President Richard Nixon signed the Occupational Safety & Health Act of 1970 (Occupational Safety & Health Administration n.d.). OSHA regulates employers through standards and enforces violations of said standards. OSHA requires employers to provide fire prevention measures such as, but not limited to, safeguards to fire hazards, training to workers on potential fire hazards, and fire safety plans.

Fire Protection

Fire protection is a large industry around the world with many different parties involved. Two methods are used to provide adequate fire protection. The first method is fire prevention, if a fire never occurs, then adequate fire protection has been achieved. Fire prevention can be provided by eliminating a hazard of a product or process, educating all involved parties on the fire hazard, or providing administrative or engineering controls to the fire hazard. If fire prevention is unsuccessful, the second method to adequate fire protection is needed, and that is to mitigate the impact of the fire event. Mitigating the effects of the fire can be done by limiting how large the fire can grow and by containing the fire to one location until the fire can be suppression.

Active Fire Protection

Active fire protection is the first line of fire protection in the event of a fire and typically comes in two forms: fire detection and fire suppression.

If a fire is to occur, it is essential to notify occupants as soon as possible to ensure adequate life safety. To do so, automatic fire detection is installed. Detector devices can be spot type detectors that only notify the local area or can be linked to a panel to notify a facility in the case of detection. Many types of automatic fire detection devices are available for use and include, but are not limited to ionization smoke detectors, photoelectric smoke detectors, combination smoke detectors, heat detectors, beam detectors, and air sampling detection.

Ionization smoke detectors – these smoke detectors contain a small amount of radioactive material between two electrically charged plates. If smoke is present, it disrupts the current of ions between the two plates and activating the alarm. This type of smoke detector is generally more responsive to flaming fires.

Photoelectric smoke detectors – these smoke detectors utilize a light source that is aimed into a sensing chamber at an angle away from the sensor. When smoke enters the sensing chamber, it reflects the light source into the sensor activating the alarm. This type of smoke detector is generally more responsible to smoldering fires.

Combination ionization/photoelectric detectors – this is a combination of functionality between ionization smoke detectors and photoelectric smoke detectors to cover a spectrum of fire scenarios. This allows a smoke detector to have the sensitivity of each time of smoke detector for both flaming and smoldering combustion.

Heat detectors – two types of heat detectors are common for use: rate-of-rise detectors and fixed temperature detectors. A rate-of-rise detector activates if the temperature increases too quickly over a specified period of time. A fixed temperature detector activates if a specified temperature is reached. These detectors have good application in facilities where ionization and photoelectric detectors may be prone to false alarms such as facilities that accumulate dust.

Beam detectors – these types of detector devices are good for use in large spaces such as atriums and warehouses. To use, a transmitter is located at one end of the coverage area and is pointed at the receiver at the other end of the coverage area. If anything happens to disrupt the transmitted beam, the detector activates.

Air sampling – air sampling smoke detector is a series of pipes (usually CPVC) with small holes at intervals of the pipe. The pipe directs back to an air sampling unit which pull air from the pipes to sample what is returned to the unit for smoke. If smoke is identified by the air sampling unit, activation occurs.

Fire suppression is also another common type of active fire protection. Suppression can provide two functions in a fire event, fire detection (if other detection means are not present or malfunctions) and suppression/containment of the fire event. Many types of fire suppression agents are in use today including, but not limited to, water, water mist, FM200, foam, wet chemical, dry chemical, NOVAC 1230, and carbon dioxide.

Passive Fire Protection

In fire protection, it is also important to contain the fire to one location and protect the structure to prevent structural damage; this is achieved through passive fire protection. Many structures and products can be used to achieve adequate passive fire protection. When the purpose is to compartmentalize a fire and prevent it from spreading to other parts of a building, this can be achieved with components such as fire walls, fire barriers, fire partitions, fire doors, and fire curtains and shutters.

Fire walls, barriers, and partitions – fire walls are structures built from the base of a building to the roof. Fire wall ratings can range from 3 h to 4 h. Fire barriers differ from fire walls as they only extend from floor to floor or floor to roof including any concealed spaces. Fire barrier ratings can range from 2 h to 3 h. Fire partitions in all respects are similar to fire barriers but have a fire resistance rating of 1 h to 2 h. Fire walls, barriers, and partitions must be constructed of materials that have been tested and rated in accordance with ASTM D 119, ISO 834-1, EN 1363-1, or AS/NZ 1530 (XL Catlin n.d.).

Fire doors – fire door assemblies must be tested in accordance with NFPA 252, UL 10B, BS 476: Part 20, or EN 1634-1. Fire doors must be installed and maintained in accordance with NFPA 80 and GAP.2.2.2 (XL Catlin n.d.).

Fire curtains and shutters – fire curtains and shutters are based on the same principle, a type of fire or smoke separator that can be stored in a hidden place that will deploy in the event of a fire and activation of the fire protection system. Fire curtains are usually made of a more flexible material, while fire shutters are made of a more rigid material, leading to fire shutters having a higher fire and smoke resistance rating. Each fire or smoke resistance rating will be dependent on the testing to have been performed on a product by an approved laboratory.

Manual Suppression

The final line of defense in fire protection is using humans to manually suppress a fire. It is likely manual suppression by an occupant of a building could occur before a fire suppression system activates but is not likely. It is more expected to see manual suppression in structures with no automatic suppression.

Fire extinguishers are one available tool to be utilized in manual suppression activities. Fire extinguishers range in sizes anywhere from 5lbs of chemical to extinguishers on carts to be moved to a fire for manual suppression. The extinguishing agents within fire extinguishers also vary depending on the recognized fire hazards in that location. Fire extinguishers follow a hazard classification system to determine the type of extinguisher to use for a given fire event.

Class A: Class A fuels are ordinary combustibles such as wood, paper, cardboard, cloth, etc.
Class B: Class B fuels are flammable liquids and gases such as gasoline, propane, etc.
Class C: Class C fuels are live electrical equipment such as printers, computers, etc.

Class D: Class D fuels are combustible metals such as magnesium, lithium, etc.
Class K: Class K fuels are cooking oils and fats common to a kitchen setting.

Fire extinguishers will be labeled with these different classifications to signify their appropriateness for a type of fire. Depending on the extinguishing agent in the fire extinguisher will determine the classification of fire it is available to extinguish. Some extinguishing agents will be capable of extinguishing more than one classification of fire and will be labeled as so (e.g., ABC fire extinguisher).

If a fire grows to a point where manual suppression by occupants or workers is no longer a safe option, the next manual suppression option is by trained fire personnel (fire departments or fire brigades). Firefighters engage to two types of manual suppression activities, interior and exterior fire attacks. For an interior fire attack, firefighters wear personal protective equipment (PPE) and enter the structure with a fire attack hose line. Firefighters will move throughout the structure to find the fire and extinguish the fire with water and in some cases foam. If the trained fire personnel determine a structure is no longer safe for an interior fire attack, they will deploy larger hose lines and begin an exterior attack in an attempt to extinguish and contain the fire from further spread to other buildings.

Life Safety

Fire prevention and fire protection are all focused around providing adequate life safety to residents, workers, visitors, customers, etc. Life safety is the primary goal of all aspects of fire protection from the fire prevention professional, to the firefighter, to the investigators. Life safety has been such an important goal to the fire protection field that NFPA has named an entire code after the fact, NFPA 101 *Life Safety Code*. This code is one of the most widely adopted and used code, not just within the United States, but also around the world. This code covers both fire prevention and fire protection features and activities.

Conclusion

The fire protection field is a large industry with many different concentrations and focuses. The hazards presented to the fire protection field are always changing and evolving as mankind moves to the future with new technologies. The fire protection field will always need to adapt and research new methods and technologies to address the endless changing hazards presented. This will always be done with the focus of life safety as the primary goal. The fire community will always firstly attempt to prevent any fire. This is usually the cheapest and easiest fire management strategy to ensure life safety. If prevention of a fire event is unachievable, then the fire community has many fire protection methods and activities available to protect human life.

First Responders: Police

Heather A. Panter
Centre for Advanced Policing Studies, Liverpool John Moores University, Liverpool, UK

Keywords
Emergency services · Firefighters · Police · EMT · Accident response · Decision-making

Definition

Typically, first responders (i.e., individuals who render aid at an emergency scene) include police officers, firefighters, rescuers, paramedics, emergency medical technicians (EMT), and any other individual responsible for emergency responses. Effective responses to emergency calls can play a critical role in the treatment of a victim, treatment of an arrestee, securing the scene, preserving the scene, and successful transfer of authority and responsibility of the scene to secondary responders.

Introduction

Initial actions undertaken by first responders set the stage for how emergencies and critical incidents are effectively managed. The main basic goals of responding first responders are to gain control of a site/situation and to manage available resources successfully (see Alison et al. 2015; Power and Alison 2017; Trenholm 2018). Further, there exist competing responsibilities of the first responder to render aid, avoid becoming a casualty, secure the scene, preserve and document the scene, and release the scene to appropriate authorities. As such, this entry focuses on the actions that the first responder – police officer – on a scene should carry out while managing competing responsibilities.

From a police perspective, anything and everything could be an emergency that requires first responder interactions. Further, police power itself is arguably essential to the construction of social order, and it is always an emergency power (Correia and Wall 2018). Therefore, police are referred to as "first line of defense" or "first responders" because of the perpetual management in emergency responses. Further, "policing" is the everyday application of emergency prerogatives while using discretion to make decisions on effective responses (Correia and Wall 2018). Police discretion involves individual judgements made by officers of which several behavioral responses maybe appropriate in specific situations. Outside of policing, discretion to other first responders (e.g., firefighters, EMTs) similarly entails how work policies, laws, operating procedures, and perspectives of safety interact with decisions on how to react, the extent of reaction, and on what occasions. Within policing, first responder discretion further entails what laws to enforce, the extent in which they should be enforced, against whom, and on what occasions (Schulenberg 2015).

Securing the Scene

The first priority of any first responder is personal safety and ensuring that the scene is made safe. Before a first responder's arrival to a scene, dispatch advises responders of any safety considerations that 911 callers have identified, but often these safety considerations are incomplete or contradictory. This creates uncertainty and leads to four questions:

1. Is there a criminal still at scene who can assault non-police personnel and police personal alike?;
2. Will relatives of a victim turn violent towards emergency workers?;

3. What kind of hazards will be present?;
4. Are there man-made or natural hazards present that can inhibit or harm first responders? (Gardner 2011).

Often police are called the "blue canaries" of first responders for several reasons. First, police vehicles are often quicker to emergency scenes due to their size and ability to negotiate heavy traffic areas and therefore they are frequently first upon scenes. Secondly, police approach fires or accidents involving potentially hazardous materials without any breathing apparatus or protective gear (Gardner 2011). Etymologically, "blue canaries" refers to the use of canaries in coalmines to detect hazardous gases. Thus, firefighters are often credited with a more conscious approach to hazards as they approach an emergency situation. Comparatively, police handle calls often "in progress" with due care and caution with a less emphasis upon risk management in static scenes (see Gardner 2011).

In non-static scenes (scenes with danger still being present), first responders must take control of the scene and focus on lifesaving activities. If human suspects are a safety concern, police officers are responsible for controlling and limiting actions of suspects, and at times, victim/witnesses. Suspects on scenes represent a higher level of concern and a higher priority due to officer-safety issues (Gardner 2011). Notably, before any lifesaving and fire rescue responses can take place, police officers must sweep scenes for suspects and render the scene safe. For example, in a shooting situation with multiple causalities, police first responders must ensure that the direct threat (the shooter) is apprehended or away from the scene before firefighters and EMTs can treat/transport victims. Further, police first responders have to ensure that victims are not suspect(s) themselves while making efforts to preserve the scene.

Preserving the Scene

For safety and forensic reasons, first responders are tasked with defining the criteria for incident boundaries. The criteria for doing so include focal points, avenues of entry and exit, and secondary scenes (Gardner 2011). Notably, initial boundaries established by first responders may change based upon reassessment by secondary responders. Because first responders establish these boundaries in non-stable environments, unlike secondary responders when the environment is more stable, reassessment by secondary responders of incident size, incident location, and further safety variables is common. For example, during a response to a homicide, the initial crime scene is often roped off farther than that initially assessed by responding homicide investigators.

Notably, regardless of the type of emergency, scene integrity should be upheld. From a police perspective, this is equated to crime scene evidence from being destroyed and contaminated (Gardner 2011). From all emergency perspectives, this is also equated to ensuring that the continuing safety of those within incident boundaries do not face additional hazards and reduce the ones that are currently present (i.e., structural hazards, chemical/bioterror hazards, mass causality situations, etc.). This process entails managing who has access to said incident boundaries and what secondary access points are viable (Gardner 2011). Additionally, an incident personnel log should be maintained to account for any possible forensic (e.g., trace evidence transfer) and safety considerations (Gardner 2011). As such, at all times, it is imperative that movement of first responders is accounted for regardless of the emergency they are facing.

First responders are also critical in determining the secondary response composition. Secondary responders, as indicated by first responders, define tactically the nature and scope of secondary response. For example, during a vehicle entrapment with hazardous chemicals, first response firefighters may request specialist fire units and EMT units to assist as secondary responders. Notably, the more complex an incident scene appears, the more likely an integrated specialist secondary response team might be required according to the assessment of first responders. When police respond to a bombing incident where structural hazards may be present, the expertise of

firefighters may be used as a primary line of defense for police and crime scene technicians (Gardner 2011). In more extreme situations, the expertise of structural engineers might be relied upon to keep the scene safe.

In mass casualty situations, a multijurisdictional response is often required. Concerns in a multijurisdictional response involve initial oversight into how to communicate and operate as a cohesive team and how resources can become quickly depleted (Gardner 2011). This became a major highlighted issue during 9/11 when police, EMT, and fire jurisdictions were unable to talk via radio to one another. While most emergency agencies have pre-event planning coordination responses, often the first responder is tasked with initially accessing risk management in multiagency responses (see Alison et al. 2015; Hu et al. 2014; Power and Alison 2017). Therefore, first responders must identify hazards, assess hazard(s) risks, control and reduce the effect of a hazard, and supervise how the hazard is initially managed with multiple emergency responders prior to releasing a scene to secondary responders (see Alison et al. 2015; Power and Alison 2017).

Releasing the Scene to Secondary Responders

Eventually, after ensuring proper documentation, first responders will have to release the scene to secondary responders (e.g., criminal investigators, EMTs, and fire fighters who must await for the scene to be secured; hazmat technicians; technical rescue technicians; utility workers; emergency volunteers; civil engineers; etc.). During this downtime, while awaiting secondary responders, first responders may begin taking notes for the documentation process. During this process, initial observations, actions upon initial arrival, and specific details about the incident assist in the relaying of vital information to secondary responders for a debriefing. Therefore, effective documentation about what the first responder knows, what they found, and what they did should be relayed to secondary responders when handing the scene over (Gardner 2011).

Conclusion

First responder actions set the stage for success and safety of secondary responders. Therefore, first responders are tasked with initial scene assessment and how sources should be allocated. During this process, first responders must ensure that they do not become a casualty, document all information, provide and coordinate emergency care, secure the incident scene and those found there, and subsequently release the scene to determined secondary responders.

Fraud Risk Management: Using Fraud Analytics to Combat External and Insider Threats

Pierre-Luc Pomerleau[1] and Mathieu Auger-Perreault[2]

Definition

Fraud is the loss of financial assets, information, or property where a victim unknowingly believes false information provided by a malicious individual or organization that stands to benefit from the false representation.

Introduction

Organizations of all sizes recognize that fraud, whether committed by malicious insiders or external threat actors, can have a significant impact on an organization's reputation and profitability as well as on customer experience. Firozabadi et al. (1998) claim fraud usually occurs when: "(a) an individual or an organization intentionally makes an untrue representation about an important fact or event; (b) the untrue representation is believed by the victim (the person or organization to whom the representation has been made; (c) the victim relies upon and acts upon the untrue representation; (d) the victim suffers loss of money and/or property as a result of relying upon and acting upon the untrue representation" (Firozabadi et al. 1998, p. 4). Fraud has been researched for decades, giving birth to fraud models that seek to understand the various factors involved in fraudulent activities, including pressure to commit fraud, the opportunity that allows the fraud to occur, and the rationalization the fraudster uses to justify his behavior.

Large corporations, such as WorldCom and Enron, have declared bankruptcy as a result of the malicious actions of insiders (Binns 2019), while others, such as the French bank Société Générale, have suffered billions in losses (Hunker and Probst 2011). With the increased popularity of e-commerce and the migration to electronic banking and payments, the external threat has become digital (Abu-Shanab and Matalqa 2015), providing fraudsters with new opportunities. Billions of records, including personal identifiable information, have been stolen as part of massive data breaches (Cheng et al. 2017). For example, in 2013, hackers stole information about 40 million Target credit cards and 70 million personal information records, while Yahoo reported that all 3 billion of its user accounts had been compromised (McMillan and Knutson 2017). More recently, the personal information of 148 million Americans was exposed in the Equifax data breach (Fleishman 2018).

Fraudsters either sell such stolen information and the tools used to extract it in illicit marketplaces (Dupont et al. 2017) or leverage the data for illegal purposes, such as using social engineering and spear-phishing attacks to trick targets into providing confidential information, perform fraudulent transactions, or make it possible to install malware on victims' computers (Butavicius et al. 2016). Spear-phishing differs from traditional phishing – which involves sending email to a massive number of individuals but expecting only a small response – in that attackers have personal information about their victims and can target specific individuals within an organization. Their emails include relevant information

about their victims, increasing the likelihood that victims (often chief executive officers, executives, or accounting and finance personnel) will click on a link and/or provide confidential information.

Data analytics has been used to prevent and detect fraud for decades, using methods that range from detection rules to artificial neural networks. Detection rules are based on expert knowledge and can be easily explained to client organizations, the management, or potential users. However, to keep up with the ever-changing tactics of fraudsters, rules must continually be added to or adjusted to remain relevant, and monitoring their effectiveness is complicated. They must also be maintained in an inventory, and their performance tracked, leading to complex and time-consuming rules management systems. While a single rule is easily explainable, having hundreds of rules nullifies that advantage (Ryman-Tubb et al. 2018).

Machine learning models have also been used to prevent and detect fraud, most notably in credit card fraud management. There are three categories of machine learning models: supervised, unsupervised, and reinforcement, with supervised and unsupervised learning the most prevalent in fraud risk management. Supervised learning algorithms, such as decision trees, logistic regression, and support vector machines, require labeled data, such as confirmed fraudulent transactions. Unsupervised learning, such as clustering, does not use labeled data and is useful in fraud risk management as it facilitates detection of anomalies. A confusion matrix can be used to assess the performance of a machine learning detection model (Ryman-Tubb et al. 2018).

Data visualization, by highlighting outliers or duplicate payments in potential fraudulent transactions, has also been used in fraud detection and investigation. Another data visualization technique that shows anomalies in a dataset is Benford's Law, which states that the distribution of numbers in many data sets, including those in nature, follows the same pattern, with "1" as their first digit 30.1% of the time, "2" 17.6% of the time, "3" 12.5% of the time, and so on. Comparing the distribution of numbers in a dataset to distribution according to Benford's Law can highlight outliers that may be indicative of fraud (Durtschi and Pacini 2004). Regardless of the analytic technique used, its performance must be tracked, and false positive and fraud detection rates are often used to assess performance (Ryman-Tubb et al. 2018). In fraud detection, a true positive (TP) is a confirmed fraud incident detected by the model. False negatives (FN) are instances of confirmed fraud that the model did not identify. False positive (FP) refers to non-fraud events that the model incorrectly identified as fraud, and true negative (TN) refers to non-fraud events that the model correctly identified as non-fraud. The fraud detection rate of a model can therefore be calculated as TP / (TP + FN), while the false positive rate can be calculated as FP / (TN + FP) (Sokolova and Lapalme 2009).

Artificial intelligence (AI), defined by Chandra and Prihastomo (2012) as creating a system by which a machine can perform tasks like a human, has also been used in fraud detection. Machine learning, a way of trying to achieve AI, is the ability of computer systems to learn and improve through experience rather than explicit instructions. Several machine learning algorithms have been developed, such as decision trees, support vector machines, and neural networks. While decision trees are easily explainable, other machine learning algorithms, despite active research, remain black boxes, which stifle their adoption rate, especially in heavily regulated industries.

Research in AI has taken place since the 1950s, with cycles of hype and "AI winters" (Menzies 2003, p. 18). Deep learning, a machine learning technique at the heart of many recent advancements in computer vision and speech recognition, is based on neural networks, which have been studied for decades. One key difference between the use of AI today and AI in the 1990s is the amount of data and computing power available. According to Schmidhuber (2007), the Internet and, more recently, the Internet of Things (IoT) are contributing factors in the vast amount of data available today. Cloud computing allows computing to be pooled, on demand, enabling machine learning techniques to be used on extensive datasets. Fraud risk management, anti-money

laundering, and cybersecurity risk management practices, combined with on-demand computing resources, benefit from the increased amount of available data.

Cloud Computing and the Rebirth of AI

The term artificial intelligence is not new. It was first used in 1956 during the Dartmouth Conference (Gryz 2013), and sparked research into how computers could be made to think like humans. In 1958, artificial perceptron was invented, increasing hopes for advancements in AI. For example, in 1965, Herbert A. Simon, a renowned economist and AI pioneer, was quoted as saying that "machines will be capable, within twenty years, of doing any work that a man can do" (Gryz 2013). However, this hopeful period was followed by a significant reduction in AI funding, called an AI winter, and then another cycle of hope and winter. Several breakthroughs in the 1990s put AI back into the mainstream. For example, in 1997, Deep Blue, a chess-playing AI program developed by IBM, defeated world champion Garry Kasparov (Campbell 1999). The 1990s also saw the rise of the World Wide Web, an invention at the heart of a level of generation of data never seen before in history, most notably through the Internet of Things (Zaslavsky et al. 2013). This large amount of data improved the possibilities for AI, as machine learning algorithms require a great deal of data to make better predictions (Gandhi et al. 2017). According to Vaquero et al.:

> Clouds are a large pool of easily available and accessible virtualized resources (such as hardware, development platforms and/or services). These resources can be dynamically reconfigured to adjust to a variable load (scale), also allowing for optimum resource utilization. This pool of resources is typically exploited by a pay-per-use model in which the Infrastructure provider offers guarantees using customized SLAs [service-level agreements]. (Vaquero et al. 2009, p. 2)

Machine learning has proven its effectiveness in many fields, and machine learning interpretability is an active area of research. However, in a heavily regulated industry, such as banking, opacity is still an obstacle to mass adoption and trust. Tulio et al. (2016, p. 1) propose two definitions of trust in a machine learning context: "(1) trusting a prediction, i.e., whether a user trusts an individual prediction sufficiently to take some action based on it, and (2) trusting a model, i.e., whether the user trusts a model to behave in reasonable ways if deployed." The authors note the importance of interpretability in getting users to adopt and trust a model and its predictions, for example, by making clear which variables or features are essential to the prediction. Prediction explanations are also useful in choosing between two models that both perform well in terms of other metrics, such as accuracy (Tulio et al. 2016).

External Fraud

External fraud can take various forms. Financial institutions have dealt with some of them for decades, with cheque fraud, identity theft, and counterfeit credit cards responsible for significant losses (Smith 2018). In the 1990s, fraud involving credit card transactions led banks to adopt fraud detection systems that evaluate the risk associated with each transaction. These systems usually combine rule management with alert management (Ryman-Tubb et al. 2018). Fraud investigators are then tasked with confirming if the transactions associated with an alert are legitimate or not. This feedback is then used to adjust models and detection rules.

Recognizing that counterfeit fraud led to significant losses, financial institutions, in partnership with various card providers, decided to invest in Europay Mastercard Visa (EMV) cards or what is referred today as chip cards. Chip cards, unlike magnetic stripe cards, use dynamic data elements to reduce the risk of counterfeiting (Anderson and Murdoch 2014). With counterfeiting opportunities for credit cards reduced by EMV, fraudsters migrated online, initiating fraudulent e-commerce transactions as well as data breaches. Some of these data breaches targeted credit card information (Smith 2018). Armed with data from credit cards, fraudsters try to either initiate fraudulent transactions or sell the

information in illicit marketplaces. However, buyers and sellers on such marketplaces know that it is only a matter of time before banks detect the fraud and cancel the cards and malicious actors have therefore begun to steal personal information, which, unlike credit card information, is not open to being changed or replaced (Dupont et al. 2017). Significant data breaches at Yahoo and Equifax resulted in billions of records becoming available in illicit marketplaces (Smith 2018), making it possible for criminals to try to open new accounts or to obtain loans and other services under stolen identities. As mentioned earlier, the information is also used to send targeted phishing emails.

Fraudsters have also migrated to wire-transfer fraud. One type of wire-transfer fraud is Business Email Compromise (BEC), in which criminals use social engineering to trick people into transferring funds to another country. Messages that appear to be from an authority figure, the CEO for example, are sent to an employee, asking that funds be moved quickly by wire transfer to an overseas country where the CEO is supposedly on a business trip. Many organizations have fallen for this crime, to the point that the Federal Bureau of Investigations (FBI) estimates that losses related to BEC amount to billions (Federal Bureau of Investigation 2018). Criminals have also targeted several banks around the world, asking them to send fraudulent wire transfers through the Society for Worldwide Interbank Financial Telecommunication (SWIFT) platform. In the last few years, there have been several cases of banks getting hacked, most notably the Bank of Bangladesh and Punjab National Bank. In the case of the Bank of Bangladesh, criminals infiltrated the bank's system and initiated close to a billion dollars in wire transfers – US$81 million was eventually lost after it was sent to bank accounts in the Philippines opened by criminals using fictitious identities (Karim 2016). In the case of Punjab National Bank, two employees used the SWIFT system to issue fraudulent letters of undertaking worth over US$1 billion (Gayathri and Mangai 2018). These cases highlight the need to take a holistic approach to fraud risk management, as both outsiders and insiders can take part in fraudulent activities. It is worth noting that the Bank of Bangladesh case, as well as other cybersecurity events such as the hack into the Bank Muscat (Musaev and Yousoof 2015), show the convergence of cybersecurity and fraud. A cybersecurity event such as a hacking incident can lead to fraud transactions. Such situations have led some organizations to create centralized fusion centers, where professionals from both fraud and cybersecurity departments share information about threats and prevention mechanisms and establish standard incident-response procedures.

Organizations have realized they need to improve their fraud mitigation measures. One key piece of the fraud management puzzle is authentication. While identification is concerned with who you are (e.g., username, email address), authentication focuses on proving that you are who you say you are. While the most popular authentication mechanism is still the password (Choubey and Choubey 2013), there are several issues with password-based authentication. First, many users have weak passwords that are easily guessable or that can be found in leaked password databases available on the Internet or the dark web. Also, users tend to have the same password for different platforms, so a malicious actor who gets access to a database of email addresses and associated passwords can try to reuse these combinations on other websites. This is what happened in the 2012 LinkedIn hack, in which millions of email addresses and passwords used to log into LinkedIn were stolen by cybercriminals (Walters 2016).

To strengthen authentication measures, organizations are moving away from a single authentication factor (something you know) to multifactor authentication: something you know (e.g., password), something you are (e.g., biometrics), or something you have (e.g., a trusted device). Biometrics can be broken into several categories, with various degrees of security and intrusiveness (Jain Ross and Prabhakar, 2004) and its use in authentication has become more mainstream in recent years, most notably through Apple's use of fingerprinting technology to unlock a phone or to pay with it. Device profiling is another component of enhanced authentication. By analyzing a

device, an organization can leverage hundreds of data points (e.g., browser type, operating system, screen resolution) and assign a risk level to a device. Based on this risk level, an enhanced authentication method can be used, for example, through SMS (short message service) or a push notification to an application on a trusted device. Authentication is one piece of the fraud mitigation puzzle; analytics is another.

Insider Threat

Insider threat is part of a new reality for public and private organizations. An insider threat is an individual (e.g., a contractor) or an employee working inside the organization who has legitimate access to critical assets and privileges based on a position of trust within the organization (Catrantzos 2012). Understanding the motivations behind fraud has been the subject of many studies, with the fraud triangle – the theory that fraud is most likely to occur when individuals encounter pressure, opportunity, and find a way to rationalize the resulting actions that do not conflict with their values – and the fraud diamond – the fraud triangle plus capability; when the fraudster do realize he has an opportunity as well as the "ability to turn it into reality" – two of the most popular approaches (Abdullahi and Mansor 2015). Numerous factors can lead an employee or an individual working inside the organization to decide to attack it. The most common are: (a) personal predisposition, (b) personal stressors, and (c) professional stressors (Ozkaya and Aslaner 2019). Insiders may attempt to profit directly from fraud or may intend to damage the company by stealing data or destroying information and critical assets or to damage its reputation by revealing sensitive, proprietary, or confidential information. The reasons for such actions are not always rational and may be related to frustrations such as a promotion they did not receive, a salary increase that did not live up to their expectations, or loss of a job.

Insider threats may also be motivated by less personal reasons, such as being paid by a competitor to sabotage activities or having built relationships with organized crime (Pomerleau 2019). Criminals may enlist employees to help commit crimes such as drug trafficking, launching a cyberattack, or physical attacks against the organization or an individual (Shapiro et al. 2018; Ozkaya and Aslaner 2019; Pomerleau 2019). Malicious employees know the level and responsibilities of employees within the organization and may leak information that assists outsiders to target another employee with a convincing email that includes proprietary data to make it look like a legitimate request (Ozkaya and Aslaner 2019). Malicious employees may also benefit from selling personal information about clients to organized crime organizations, which use this information to apply for credit cards and loans.

An insider threat may also occur when an employee fears being penalized by his employer for an innocent mistake. For instance, an employee might be a victim of a phishing fraud scam that makes it possible for the hacker to encrypt all the information on the employee's work computer. The attacker may then ask the employee to pay a ransom to get his data back, and if the employee is too embarrassed to discuss the matter with his supervisor or to report the incident to the internal security department, he or she may pay the ransom, leading to additional ransom demands (Gordon 2018). Even if the employee regains access to the data, the software, malware, or Trojan horse used by the hacker may still be in the organization's system, making it possible for the attacker to access other critical information or systems (Gordon 2018). If such a security incident takes place, and the organization is not aware of it in time to take remedial actions, it may lead to more critical business interruptions, losing access to crucial information, or problems with significant business dealings that will significantly impact the organization's bottom line as well as its reputation (Gordon 2018).

Ozkaya and Aslaner (2019) used Accenture survey data about cyberattacks on various organizations to estimate the extent of financial losses related to cybercrime and found that insider threat is now the most common type of cybercrime and leads to the highest average losses. In 2017, the average loss per incident was US$173,516, and

the authors suggest that it usually takes 50 days to recover from such an attack. Indirect costs, production loss, and the cost of business downtime also need to be taken into consideration in managing insider threat cases (Lobo 2019). When responding to such an attack, a forensic investigation may be necessary, various legal procedures may be needed to recover the stolen information, and a root cause analysis is recommended best practice. Such a postmortem analysis makes it possible to understand why the incident occurred and what additional preventive and investigative controls should be implemented to avoid a similar situation in the future. Insider threats incidents may also lead to the creation of a crisis cell within the organization, as the malicious employee may have stolen customers' personal information. If this is the case, the organization will need to communicate with affected customers and take appropriate mitigating measures to protect the identity and privacy of their clients.

To protect themselves, organizations need to have the proper tools in place. These tools might be intrusion prevention and detection systems, data loss prevention systems, or security incident management (SIEM) systems to monitor logs and detect suspicious activities in employees' behavior. Fraud detection capabilities, rules, and models that are currently used to identify external fraud can be leveraged to detect insider threat. For example, security professionals need to understand what regular actions or behaviors are and what should be considered suspicious. For instance, is it normal for an employee working a regular day shift schedule to try to get access to a confidential file at night from an unknown IP address while connected through the virtual private network (VPN)? Is it normal for an employee leaving the organization to download many files onto a USB key on his last day at work? If an employee is sending multiple emails with large documents attached from his corporate email to a personal email account, it should trigger an alert for review to see what actions should be taken. When analyzing a suspicious occurrence, an investigation analyst might ask if an employee with high-privilege access has shared his login access with a hacker, making it easier for an outsider to get access to confidential data and systems (Ozkaya and Aslaner 2019).

Various strategies and techniques can be used to prevent and detect insider threat before an unfortunate incident occurs. Unfortunately, this type of threat management is far from being a perfect science as such threats are incredibly challenging to prevent. Organizations can use data analytics, machine learning, and intelligence sharing within their organization as well as with external partners (Pomerleau 2019). Vetting personnel through background checks before hiring, job rotations within the organization, and making sure to apply least privileges and separation of duties rules are still the foundational prevention measures that every organization should implement (Ozkaya and Aslaner 2019). Different tools and data analysis techniques, such as those mentioned earlier, can also help identify abnormal behavior. While small organizations may not have security teams dedicated to managing insider threats, these organizations should still try to have minimal prevention and detection capabilities in place to detect suspicious transactions or anomalies in behavior that do not fit with regular employee activities. Within large organizations, fraud investigation, corporate security, and cybersecurity teams should share as much intelligence as possible as this is one of the most efficient and effective ways of managing insider threat cases. A dedicated team should be responsible for data analytics, rules, and models as this puts it in a better position to identify potential insider threat behavior and makes it possible to act before it is too late to protect the organization.

Conclusion

In this entry, we look at the evolution of fraud risk from the perspective of both external fraud and insider threat. We also discuss how data analytics has been used in fraud risk management, as well as the key indicators that should be utilized to evaluate performance. We look at how AI has evolved since its beginnings and how the amount of data and computing power has changed in the past 15 years. While there is no silver bullet in

fraud risk management, recent advances in AI are promising. These advances will, however, also be used by those seeking to commit fraud. The cat and mouse game played by fraud professionals and criminals will continue, meaning that organizations need to invest in data analytics techniques such as machine learning and AI to mitigate risks for their organizations as well as to protect their customers.

Geographic Information Systems (GIS) Applications in Emergency Management

Hung-Lung Wei
Department of Security, Fire, and Emergency Management, John Jay College of Criminal Justice, CUNY, New York, NY, USA

Keywords
GIS · Emergency management · Natural hazards · Technological hazards

Definition

Burroughs (1986) defined GIS as "a powerful set of tools for collecting, storing, retrieving, transforming, and displaying spatial data from the real world" (quoted in Waugh 2002, p. 277). In addition, Star and Estes (1990) stated GIS as "An information system that is designed to work with data referenced by spatial or geographic coordinates. In other words, a GIS is both a database system with specific capabilities for spatially referenced data, as well as a set of operations for working with the data" (p. 2).

Introduction

Geographic Information Systems (GIS) is a computer-based information system that can be utilized to acquire, store, display, and analyze spatial data; and it is widely used in the field of emergency management. Drabek (1991) defined emergency management as "the discipline and profession of applying science, technology, planning and management to deal with extreme events that can injure or kill large numbers of people, do extensive damage to property, and disrupt community life" (p. xvii). Thus, emergency managers should apply best methods to mitigate for, prepare for, respond to, and recover from the risks of catastrophic events. The importance of GIS has been recognized by many local, state, and federal government officials, private sectors, and hazard scholars who have applied a variety of GIS tools to deal with issues of emergency management. Specifically, this entry describes some examples of GIS application for natural and technological hazards.

Natural Hazards

In the past decades, natural hazards (e.g., hurricanes, tornadoes, tsunamis, earthquakes, volcanic eruptions, floods, landslides, wildfires, etc.) have caused a number of casualties and economic losses

© Springer Nature Switzerland AG 2021

https://doi.org/10.1007/978-3-319-70488-3

worldwide. Federal Emergency Management Agency (FEMA) developed a GIS-based software – Hazus – to estimate potential losses from earthquakes, floods, and hurricanes (see https://www.fema.gov/hazus). This GIS-based software can be utilized for four phases of emergency management – mitigation, preparedness, response, and recovery – and it is widely adopted and used by emergency management organizations in the United States, Singapore, Canada, Australia, and Pakistan (Islam and Ryan 2015). Moreover, in 2003, FEMA initiated a Flood Map Modernization (Map Mod) program, as part of the National Flood Insurance Program (NFIP) to update the flood maps and to provide accurate flood risk data in GIS format on the Digital Flood Insurance Rate Maps (DFIRMs). Through this program, 95% of the paper flood maps were eliminated and transformed into a GIS-based digital inventory of flood hazard data (Islam and Ryan 2015). The US National Oceanic and Atmospheric Administration (NOAA) developed the Sea, Lake and Overland Surges from Hurricanes (SLOSH) model to estimate storm surge heights resulting from historical, hypothetical, or predicted hurricanes by taking into account the atmospheric pressure, size, forward speed, and track data (see https://www.nhc.noaa.gov/surge/slosh.php). Based on this SLOSH model, in 2016 NOAA created the Potential Storm Surge Flooding Map program to predict risk areas associated with coastal flooding from storm surge (see https://www.nhc.noaa.gov/surge/inundation/). Regarding the earthquake hazard, the US Geological Survey (USGS) developed an Earthquake Hazards Program that provides earthquake data including real-time and historic earthquake catalogs, GIS data, and seismic hazard analysis tools that create customized hazard maps to assess individual and overall hazard (Islam and Ryan 2015).

In addition to government efforts, a substantial number of hazard scholars have utilized GIS tools to determine the proximity of natural hazard sources, and they found that people's perceived risk is associated with the proximity of natural hazard sources – volcano (Blong 1984; Gregg et al. 2004; Johnston et al. 1999; Wei and Lindell 2017), earthquake (Palm et al. 1990), and hurricane (Baker 1991; Lindell et al. 2005; Lindell and Hwang 2008; Peacock et al. 2005; Zhang et al. 2010).

Technological Hazards

Like natural hazards, technological hazards (e.g., toxic chemicals, radiological and nuclear materials, flammable materials, and explosives) can cause injuries, fatalities, and property damages. In the United States, hazardous materials (hazmat) are regulated by many federal agencies such as Department of Transportation (DOT), Environmental Protection Agency (EPA), Nuclear Regulatory Commission (NRC), etc.; however, FEMA and US Coast Guard are responsible for emergency responses to hazmat incidents. The hazmat is categorized as "explosives, gases, flammable liquids, flammable solids, oxidizers and organic peroxides, toxic (poisonous) materials and infectious substances, radioactive materials, corrosive materials, and miscellaneous dangerous goods" (Lindell et al. 2006, p. 139). Emergency managers are required to understand the community-wide hazards associated with fires arising from flammable gases and hazards that could result from a toxic chemical release. Furthermore, it is necessary for emergency managers to collaborate with regional laboratories and state and federal public health agencies to identify the agent, to treat the victims, and to decontaminate the incident site (Lindell et al. 2006). In response to chemical emergencies, EPA and NOAA developed a modeling program called Areal Locations of Hazardous Atmospheres (ALOHA) that is designed to evaluate releases of hazardous chemical vapors and predict threat zones associated with hazardous chemical releases such as toxic gas clouds, fires, and explosions (see https://www.epa.gov/cameo/what-cameo-software-suite#ALOHA). The scenarios and threat zones can be displayed on MARPLOT, which is a GIS-based mapping platform for this system (see https://response.restoration.noaa.gov/marplot).

Research on Toxic Release Inventory (TRI) and Superfund Sites

Bowen and others (1995) utilized 1990 census tract data and GIS tools to study the status of environmental inequity in the state of Ohio. They discovered that there existed high correlations between the distributions of minority populations and the locations of toxic release inventory (TRI) facilities within the state of Ohio, especially concentrated in urban areas (Bowen et al. 1995). Furthermore, Glickman and Hersh (1995) analyzed differential levels of risk from TRI facilities in the Pittsburgh area and found that three groups were at higher risks than the general population: all blacks, all poor, and the elderly.

Stretesky and Hogan (1998) investigated the spatial relationship between Superfund sites and the racial and socioeconomic characteristics in order to detect the extent of environmental injustice in the state of Florida. Their research suggested that African-Americans and Latinos tended to reside near Superfund sites, but indicators of income and poverty were not significantly correlated with the locations of Superfund sites. Maranville and others (2009) utilized an area-apportionment method, GIS tools, and statistical techniques to determine the correlation between the demographic and socioeconomic characteristics of a community and its proximity to the Superfund sites in Illinois. They discovered that the proportions of minority populations within 1-, 2-, and 5-mile radii buffer zones of Superfund sites were significantly higher than those outside the buffer zones. Their investigations suggested that race, instead of class, was the major cause of environmental injustice (Maranville et al. 2009).

Conclusion

Even though we cannot control all natural and technological hazards, we can still utilize GIS tools to identify potential hazard exposures, map social vulnerability, and apply protective actions for saving our lives. As Tomaszewski (2014) noted, hazard mitigation for GIS often requires interdisciplinary collaborations in earth science, sociology, and environmental science, and those mitigation activities must be guided by the underlying scientific principles, processes, and vulnerabilities. Indeed, using GIS not only allows governmental agencies and institutions to analyze and address issues of emergency management but also demonstrates a great way to promote risk communications with the public.

Environmental hazards · Health effects · Chemical, Biological, Radiological, Technological · Physical · Flint

Definition

Hazardous environments are those where one or a group of toxic chemical, biological, radiological, technological, or physical agents in the environment may kill or negatively impact the health of those exposed to them, particularly children (World Health Organization n.d.).

Introduction

Our quality of life and years of healthy living is dependent on maintaining healthy environments. Globally, around 23% of all deaths and over a quarter (26%) of deaths among children 5 years and younger are due to environmental hazards (Department of Health and Human Services 2014). As far as environmental hazards are concerned, we live in a world of contradictions. As human beings we require clean environments to live a good quality of life, but in our daily living, we are the principal drivers of hazardous environments by the way we live and work.

For instance, whether on purpose or because of a lack of knowledge, lapses in judgment or malfunction in technical systems or in the built environment often result in harmful environmental conditions (Department of Health and Human Services 2014). We release hazardous environmental pollutants in the air, waterways, and drinking water supply. Pollutants such as pesticides, Chlorofluorocarbons (CFCs), secondhand tobacco smoke, industrial and home chemicals contaminate the atmosphere. Chemicals including lead, polychlorinated biphenyls, microbes, and suspended matter contaminated drinking water, and toxic waste like sludge contaminate the sea, rivers, and lakes. These substances have adverse effects on our health. In addition, naturally occurring factors including climate change, earthquakes, landslides, ozone build-up put our life and health in danger (Department of Health and Human Services 2014).

Chemical Hazards and Their Effects

Chemical, environmental hazards can result in short and long consequences to those exposed to them (World Health Organization Institute n.d.).

These agents include nerve agents that can enter the body through the skin or lungs and affect the nervous system (e.g., sarin, VX, and VR), and systemic agents such as hydrogen cyanide that enter the bloodstream either directly or indirectly and are transported throughout the body (Ganesan et al. 2010). Also, respiratory agents including chlorine are inhaled and can cause damage to the lungs. Moreover, blister agents like mustard gas damage the skin (Ganesan et al. 2010).

Depending on the severity of the exposure, impacts may include temporary illness or injury, permanent medical conditions, or death. For instance, Grandjean et al. (2007) found that reproductive health, as well as embryonic, fetal, and infant development, is susceptible to chemical hazards. Toxic exposures to chemical pollutants during human developmental stages can cause disease and disability not only in infants and children but across the entire human life cycle. In adults, chemical hazard exposure is linked to spontaneous abortion, congenital malformations, lowered birthweight, physical or mental illnesses that either remain or only become evident, months or years of exposure (WHO Institute n.d.; Grandjean et al. 2007). Some chemical agents have been strongly linked to cancer in humans (WHO Institute n.d.). Short-term effects include stomachaches, rashes, headaches, and nausea (WHO Institute n.d.). Chemical agents can enter the digestive system via contaminated food or drinking water, by hand to mouth contact from touching contaminated surfaces, or by swallowing respiratory mucus containing accumulated larger aerosol particles in the nose, throat, and upper airways (WHO Institute n.d.).

Biological Hazards and Their Effects

Biological hazards are disease-causing microorganisms and pathogens that can multiply within a human host and cause an infection (Bacon and Sofos 2003). These agents include bacteria, viruses, fungi, other microorganisms that could cause grave injury to individuals or a group because many microbes reproduce rapidly and require minimal resources to survive (OSHA n.d.). Infections typically occur because of airborne exposure through inhalation (e.g., with Bacillus species, anthrax spores) and skin contact with contaminated surfaces (as with MRSA and Staph). Some biological agents can be spread from one individual to another (Ebola hemorrhagic fever [EHF]) (OSHA n.d.). Contamination is also possible through ingestion of contaminated food or water as is the case with *E. coli*, which causes gastrointestinal infection (OSHA n.d.).

Radiological Hazards and Their Effects

Radiation is energy released from light, heat, sound, and charged particles that can cause direct or indirect damage to the body (Alameda County Public Health Department 2013). We experience some level of radiation exposure during the ordinary course of everyday living (e.g., sunshine). We are also exposed to human-made radiation (from microwave ovens) and medical sources (from x-rays), which in sufficiently large dosage can cause unhealthy health effects. Large amounts of radiation can occur in places such as a nuclear power plant accident or a terrorist attack (Alameda County Public Health Department 2013). Radiation exposure and radioactive contamination can occur if radioactive materials are released into the environment because of an accident, an event in nature (e.g., an earthquake), or an act of terrorism (CDC 2018). Such a release could expose people and contaminate their surroundings and personal effects. Radioactive contamination can occur when radioactive material is deposited on or in an object or a person.

Radiological hazards can contaminate drinking-water sources because of the mining industry and hydraulic fracturing or radionuclides from the medical or industrial enterprise that use radioactive materials (World Health Organization n.d.). Radioactive materials released into the atmosphere can cause air, water, surfaces, soil, plants, buildings, or even people, or animals to become contaminated (CDC 2018). There are some types of radioactive materials that stay in the body and are deposited in different organs.

Others are eliminated from the body in blood, sweat, urine, and feces (CDC 2018).

A contaminated person has radioactive materials on or inside their body. When radioactive materials enter the body either through an open wound, swallowing, or breathing or are absorbed through the skin, it is referred to as internal contamination (CDC 2018). Alternately when contact is external to a person's body such as with radioactive dust, powder, or liquid, which meets a person's skin, hair, or clothing, it is referred to as external contamination (CDC 2018). External contamination can become contamination internally if radioactive material gets into their bodies from these sites (CDC 2018).

Those exposed to large doses of radiation can display signs of acute radiation syndrome (ARS), or radiation sickness, a severe short-term illness whose symptoms include nausea, vomiting, headache, and diarrhea (CDC 2018). After the initial symptoms, a person usually looks and feels healthy for a period. However, then he or she becomes ill again often showing variable symptoms and severity that change over time depending on the radiation dosage received (CDC 2018). If death occurs, it is usually from the destruction of the person's bone marrow, which then leads to infections and internal bleeding (CDC 2018). Other less severe symptoms of radiation contamination include loss of appetite, fatigue, fever, nausea, vomiting, diarrhea, and possibly even seizures and coma. The amount of radiation an individual can absorb is called the radiation dose (CDC 2018). The lower the dose, the more likely it is for the individual to survive.

Technological Hazards and Their Effects

Hazardous environmental effects because of technological hazards are human-caused events that negatively impact people, their livelihood, and their property. Technological hazards are usually the result of increased opportunities for human error inherent in the use of harmful materials such as hazardous waste, sloppy craft, machine failure, or failure in routine monitoring (FEMA n.d.).

Often, little or no warning precedes technological incidents (FEMA n.d.). In many cases, victims may not know they have been affected until many years later. For example, health problems caused by hidden toxic waste sites – like that at Love Canal, near Niagara Falls, New York – surfaced years after initial exposure (FEMA n.d.). For example, A series of reports on the health effects of the Love Canal landfill disaster including a study commissioned by the NYS Department of Health in 2008, nearly 40 years after the disaster, found excess lung cancer kidney, bladder, and other cancers among those exposed to chlorinated benzenes and aniline compounds (Division of Environmental Health Assessment Center for Environmental Health 2008). Moreover, the rates of congenital malformations exceeded those for the general population and indicated potential chemical exposure as a child (Division of Environmental Health Assessment Center for Environmental Health 2008).

Technological hazards have the potential to happen suddenly and impact a low to moderate number of people like the Concorde airline crash in July 2000 that killed over 100 people, or the pedestrian bridge collapsed at Florida International University in Miami on March 15, 2018, that killed eight people. Others have the potential to impact large populations severely and to go on for extended periods as in the Three Mile Island, Pennsylvania, nuclear plant accident in 1973. Among other things, that incident caused elevated cancer levels of those living within a 10-mile radius of the incident and halted the development of nuclear power industry for 30 years in the USA (see Amadeo 2018).

Physical Hazards and Their Effects

Physical agents are "[a]ny phenomenon that threatens, or causes damage and destruction to people's lives, livelihood, their property and communities" (Watson 2015) because of their geographic, social, and economic vulnerabilities. A natural hazard is one produced by environmental process such as storms, floods, earthquakes, and volcanic eruptions (Watson 2015). Therefore,

hazardous environments may result from naturally occurring phenomena such as crustal (tectonic) movement such as earthquakes and resultant hazards such as shaking, landslides, tsunami; lava flows, mudflows, pyroclastic, and ash fallout volcanic hazards; and types of the eruption and their products (Watson 2015). Moreover, mass movements that result from slope instability that causes avalanches, rock slides, rock falls, landslides, and associated hazards can cause physical threat to populations living in their paths. Further, atmospheric disturbances associated with tropical storms such as cyclones and tornadoes and related hazards including storm surges, coastal flooding, severe river floods, landslides, high winds, pressure imbalances may pose a physical threat to life, property, and livelihood of populations they impact (Watson 2015).

Physical hazards can cause sedimentation in the water supply. Sediments and particulates can also include pipe materials, pipe liner materials, sloughed biofilms, or iron and manganese films (Watson 2015). Suspended or resuspended sediments can contain toxic chemicals or can have pathogens attached and can co-transport other hazards (World Health Organization n.d.), leading to poor ground and surface water quality. Concerns are increasing globally about both drinking water and recreational waters and the effects of chemical, biological, radiological, and physical agents on it (Watson 2015).

The Case of Hazardous Environmental Effects from Drinking Water in Flint, Michigan

The 2014–2016 water crisis in the city of Flint presents an example of the confluence of chemical, biological, technological factors resulting in harmful environmental effects to a group of people in the United States. The case is deemed one of the most significant public health failures of modern water supply in the USA (See Butler et al. 2016). It garnered public outcry and resulted in action at federal, state, and local levels, but not before over 8000 children were estimated to have been impacted by high lead levels in the Flint water supply.

The aging water distribution system in Flint contained a high percentage of lead pipes and lead plumbing, with estimates of lead service lines ranging from 10% to 80% (Hanna-Attisha et al. 2016; Jurkiewicz 2016). This situation along with cost-cutting measures during the 2010 recession in the United States created conditions where sections of Flint's population were exposed to detrimental effects of contaminated water. In its cost-saving efforts, the city decided to change water sources from the Detroit to the more corrosive Flint River. This decision proved to be a mistake.

Testing between October and December 2015 revealed that blood lead levels (BLLs) in children increased significantly. In the areas where lead levels in the water were at their highest, the BLLs in tested children increased by about 2.5 times previous levels (CNN 2018). Approximately 6% of the samples provided by Flint residents in January 2016 contained lead levels well over 15 parts per billion (ppb), which surpasses the federal action level (Hanna-Attisha et al. 2016; CNN 2018). The highest lead levels measured exceeded 5000 ppb. In some premises, both lead and copper levels were at critically high levels (CNN 2018). The aging Flint water distribution system contained a high percentage of lead pipes and lead plumbing, with estimates of lead service lines ranging from 10% to 80% (Hanna-Attisha et al. 2016; Jurkiewicz 2016).

In September 2014 three water alerts were issued, and another three boil water alerts were issued in a 22-day period in August 2015 as the bacterium *E. coli* had exceeded regulatory limits (Jurkiewicz 2016). As a result, the dosage of the disinfectant chlorine was increased, which resulted in violations for total trihalomethanes (TTHMs), which is cancer causing and a byproduct of the reaction of chlorine with the naturally occurring organic matter.

Drinking water that is inadequately treated or disinfected or that passes through an improperly maintained distribution system may also pose a health risk. Drinking water need only contain small amounts of some contaminants (copper, Mercury, Copper, lead) to be harmful if consumed (EPA 2017). Water quality concerns are increasing globally and include concerns for drinking as well as recreational water.

Lead is a well-established threat to children and pregnant women, but the Safe Drinking Water Act does not regulate lead in drinking water. Instead, the Clean Water Act (CWA) regulates lead in drinking water. The CWA prohibits anyone from discharging pollutants, including lead, through a point source into a water of the United States unless they have a National Pollutant Discharge Elimination System (NPDES) permit (EPA 2016; see also the US Lead and Copper Rule). Copper and lead enter our drinking water primarily through plumbing materials (EPA 2016). Exposure to lead and copper is potentially deadly and may cause health problems ranging from stomach distress to brain damage (EPA 2016). Lead exposure in children may result in anemia, kidney damage, colic, muscle weakness, and brain damage (Butler et al. 2016). Exposure to the fetus during pregnancy can result in fetal death, premature delivery, low birth weight, and lower intelligence in later childhood (Butler et al. 2016).

Regulating Hazardous Environments

In the United States, regulation of hazardous environmental effects occurs at the local, state, and federal levels. For instance, in the case of drinking water, the Safe Drinking Water Act is the chief federal law that regulates our potable water supplies. The Environmental Protection Agency sets drinking water standards and oversees states, municipalities, and water suppliers who implement those standards (EPA 2018). The EPA supports municipal wastewater treatment plants and participates in pollution prevention efforts meant to protect watersheds and other sources of drinking water (EPA 2018).

The Safe Drinking Water Act sets up multiple barriers against pollution and ensures the highest quality of drinking water. These barriers include source water protection, treatment, distribution system integrity, and public information (EPA n.d.). Public water systems must ensure that contaminants in drinking water do not exceed the stipulated standards (EPA n.d.). When the water quality does not meet these standards, it is the water supplier's responsibility to notify its customers (EPA n.d.). Many water suppliers now are also required to prepare annual reports for their customers, who are expected to work with local water suppliers to set priorities, make decisions on funding and system improvements, and establish programs to protect drinking water sources (EPA n.d.).

Besides, every state must assess its drinking water sources (rivers, lakes, reservoirs, springs, and groundwater wells) under the Source Water Assessment Program to identify potential contamination sources and determine how susceptible the sources are to these threats (EPA n.d.). Moreover, per the Stage1 Disinfectants and Disinfection Byproducts Rule and the Interim Enhanced Surface Water Treatment Rule, the EPA is required to strengthen protection for microbial contaminants (EPA n.d.).

Conclusion

Maintaining healthy environments is central to our quality of life and years of healthy living more generally. Often poor critical public infrastructure, poor decision-making, inadequate regulatory oversight, human error, and financial vulnerability lead to hazardous environmental conditions and unhealthy effects. The water crisis in Flint, Michigan, is just one example of the increasing hazardous health effects from environmental contamination occurring globally. Human beings need to reconsider how we relate to the environment and the impacts that our actions on it. Public policy and their enforcement have worked to regulate our behavior regarding the use and abuse of our natural environment, but even the policies must incorporate a fundamental reconsideration of how human beings interact with their environment in a more systemic and sustainable way.

HAZMAT

Michael K. Lindell
Department of Urban Design and Planning, Institute for Hazards Mitigation Planning and Research, University of Washington, Seattle, WA, USA

Keywords
Extremely Hazardous Substance (EHS) · Inhalation hazard · Vulnerable zone (VZ) · Level of concern (LOC) · Atmospheric dispersion

Definition

Hazardous materials are substances "capable of posing unreasonable risk to health, safety and property" (949 CFR 171.8).

Introduction

Hazardous materials (commonly known as *hazmat*) are regulated by a number of federal agencies, including the Department of Transportation (DOT), Environmental Protection Agency (EPA), Nuclear Regulatory Commission (NRC), and Occupational Safety and Health Administration of the Department of Labor. In addition, the Coast Guard and Federal Emergency Management Agency of the Department of Homeland Security have responsibilities for emergency response to hazmat incidents. Because these agencies have different responsibilities, they have correspondingly different definitions of hazmat.

Hazmat regulations cover a wide range of issues, but this entry focuses on emergency response to unplanned releases that pose a threat to the general public. Thus, this entry does not address the management of chronic chemical pollution under the Toxic Substances Control Act and Pollution Prevention Act; hazardous waste under the Resource Conservation and Recovery Act; hazmat cleanup under the Comprehensive Environmental Response, Compensation, and Liability Act; protection of workers engaged in hazardous waste operations and emergency response or oil spill preparedness and response under the Oil Pollution Act; and the Spill Prevention, Control, and Countermeasure Rule.

Emergency response to hazmat incidents has long been recognized to be a responsibility of local emergency responders in public safety agencies such as fire and police departments. These agencies can provide a satisfactory response to minor incidents, especially when they follow the DOT's *Emergency Response Guidebook* (DOT 2016) in making protective action decisions. However, the 1984 toxic chemical release in Bhopal India called attention to the need for comprehensive planning involving cases of major releases. Thus, the 1986 Emergency Planning and Community Right to Know Act (EPCRA, also known as Title III of the Superfund Amendments and Reauthorization Act – SARA Title III) required each state to establish a State Emergency Response Commission (SERC) and Local Emergency Planning Districts, each of which would have a Local Emergency Planning Committee (LEPC).

LEPCs are expected to work with local facilities that are storing more than the maximum allowable amount of chemicals designated by the EPA as extremely hazardous substances (EHSs). Specifically, this collaboration requires identifying the EHSs stored onsite and the quantities of those substances. In addition, it requires computing the radius of vulnerable zones (VZs) around the facilities and developing plans for responding to releases of those EHSs (NRT 1988, 2001). In the longer term, local jurisdictions should promote safe land use practices to ensure that high-density residential and commercial land uses are located outside the VZs for fixed-site facilities and are adequately separated from transportation routes where high volumes of hazmat are carried. High priority should be given to facilities, such as schools, hospitals, and nursing homes, that house vulnerable population segments lacking physical mobility or ready access to evacuation vehicles (see ▶ "Emergency Management: Evacuations"). Local jurisdictions

should also work with energy utilities to encourage the reduction of air infiltration in new structures and retrofits of existing structures because this will save energy in the short run and also support sheltering in-place during a hazmat release (see ▶ "Emergency Management: Shelter In-Place").

Hazmat Release Sources

Planners typically expect to find hazmat produced, stored, or used at fixed-site facilities, such as petrochemical and manufacturing plants, but these materials are also found in warehouses (e.g., agricultural fertilizers and pesticides), water treatment plants (chlorine is used to purify the water), and breweries (ammonia is used as a refrigerant). Moreover, hazmat is transported from one location to another by a variety of modes – ship, barge, pipeline, rail, truck, and air. In general, the quantities of hazmat on ships, barges, and pipelines can be as large as is stored at many fixed-site facilities, but usually the amounts are smaller for other modes of transportation, decreasing in size from rail to truck to air. Small- to moderate-sized releases of hazardous materials at fixed-site facilities are occupational hazards but often pose little risk to public health and safety because exposure resides entirely within the facility boundaries. However, releases of this size during hazmat transportation can be a public hazard because passersby can easily enter the risk area and become exposed. The amount actually released is often much smaller than the total quantity available in the container, but prudence dictates that planning processes assume the plausible worst cast of complete release within a short period of time (e.g., 10 min in the case of toxic gases).

Hazardous Materials Classification

There are thousands of chemicals in commercial use, but they can be categorized into nine classes based on their chemical and physical properties.

Explosives

Explosives cause casualties and property damage by overpressure from atmospheric blast waves and flying debris. Destructive effects from quantities found in transportation can be felt as much as a mile (1.6 km) or more away from the incident site.

Flammable Gases

Flammable gases such as liquefied petroleum gas (LPG) can travel downwind after release until they reach an ignition source, such as the pilot light in a water heater or the ignition system in a car. At distances of 0.5 miles (0.8 km) or more, the gas cloud can erupt in a fireball that flashes back toward the release point. Explosive rupture of gas containers can launch fragments up to 1 mi (1.6 km), so evacuation out to this distance is advised if there is a fire.

Flammable Liquids

Flammable liquids, such as gasoline, present a similar threat as flammable gases, in that a volatile liquid (one that rapidly produces much vapor) can travel toward an ignition source and erupt in flames when an ignition source is reached. When a flammable liquid is dispersed on land, there should be a downwind evacuation of at least 0.2 mi (0.3 km). A flammable liquid that floats downstream on water could be dangerous at even greater distances. A fire should stimulate consideration of an evacuation of approximately 0.5 mi (0.8 km) in all directions.

Flammable Solids

Flammable solids are less dangerous than flammable gases or liquids because they do not disperse over such wide areas. A large spill requires a downwind evacuation of 300 ft (0.1 km), but a fire should produce an evacuation of 0.5 mi (0.8 km) in all directions.

Oxidizers and Organic Peroxides

These substances do not burn but are hazardous because they promote combustion. A large spill should prompt a downwind evacuation of 0.3 mi (0.5 km), and a fire should initiate an evacuation of 0.5 mi (0.8 km) in all directions.

Toxic Materials and Infectious Substances

Toxic (poisonous) materials are hazardous when inhaled into the lungs, ingested into the stomach by means of contaminated water or food, or absorbed through the skin. Of these exposure pathways, inhalation hazard is typically the greatest concern because high concentrations can kill in a matter of seconds. Moreover, chemical contamination of victims could pose problems for volunteers and professionals providing first aid and transporting victims to hospitals. These chemicals vary substantially in their volatility and toxicity, so protective action distances following a spill or fire during a transportation incident must be determined from the Table of Protective Action Distances in the *Emergency Response Guidebook*. Protective action distances for releases from fixed-site facilities are more complex and are addressed below. Infectious substances have rarely been significant to date, but the potential for large-scale terrorist attacks should be of concern to emergency planners.

Radioactive Materials

With the exception of nuclear power plants, the planning for which is supported by guidance from NRC (1980), releases of radioactive materials are likely to involve only small quantities. Nevertheless, even a few grams of a lost radiographic source for industrial or medical X-rays can generate a high level of public concern. Here also, the recently recognized threat of terrorist attack from a "dirty bomb" that uses a conventional explosive to scatter radioactive material over a wide area deserves planners' attention because of the potential for long-term contamination of central business districts. A large spill should prompt a downwind evacuation of approximately 300 ft (0.1 km), and a fire should initiate an evacuation of approximately 0.2 mi (0.3 km) in all directions.

Corrosive Materials

Corrosive materials, which can be either acidic or alkaline, cause chemical burns, but the substances in this class that are most frequently used and transported are not highly volatile. Thus, the geographical area affected by a spill is likely to be no greater than approximately 300 ft (100 m) unless the container is involved in a fire or the hazmat enters a waterway (e.g., via storm sewers). These chemicals vary substantially in their volatility and toxicity, so evacuation distances following a spill or fire must be determined from the Table of Protective Action Distances in the *Emergency Response Guidebook*.

Miscellaneous Dangerous Goods

This class comprises a diverse set of materials such as air bags, certain vegetable oils, polychlorinated biphenyls (PCBs), and white asbestos. Materials in this category are low to moderate fire or health hazards to people within 30–80 ft (10–25 m).

Airborne Hazmat Dispersion

The spread of an airborne release is defined by the hazmat's chemical and physical characteristics, its release characteristics, the topographic conditions in the release area, and the meteorological conditions at the time of the release. A hazmat's chemical and physical characteristics are its volatility (the rate at which the chemical becomes airborne per unit of time), buoyancy (whether it tends to flow into low spots because it is heavier than air), toxicity (the biological effect due to cumulative dose or peak concentration), and physical state – whether it is a solid, liquid, or a gas at ambient temperature and pressure.

Release characteristics are defined by the chemical's temperature and pressure in relation to ambient conditions, its quantity (measured by the total weight of the hazmat released), its release rate (in pounds per minute), and the surface area of the spilled pool if the substance is a liquid. Temperature and pressure are important because the rate at which the chemical disperses in the atmosphere increases when these parameters exceed ambient conditions. The release rate is important because it determines the concentration of the chemical in the atmosphere. Specifically, a release rate at the high end puts a large volume of

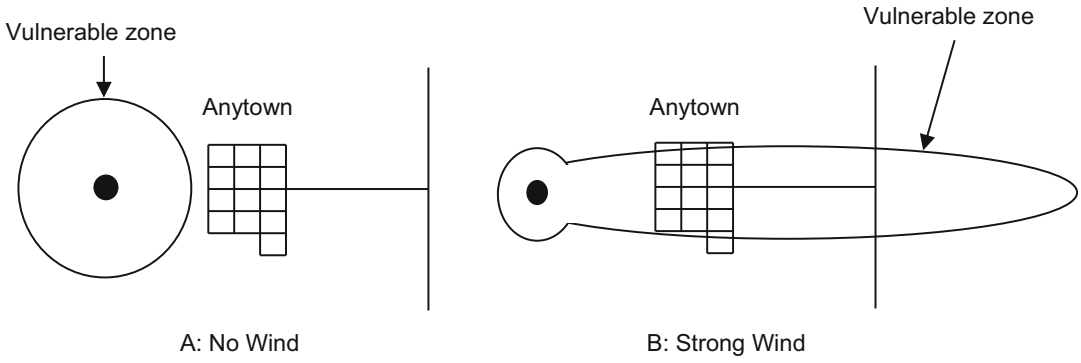
chemical into a given (limited) volume of air, thus increasing its concentration (the amount of chemical divided by the volume of air in which it is contained).

Topographical conditions relevant to liquid spills or dense gases are the slope of the ground and the presence of depressions. Steep slopes allow a liquid to rapidly move away from the location of the spill. Both flat slopes and depressions decrease the size of a liquid pool's surface area and, in turn, reduces the rate at which vapor is generated from it. Thus, hazmat facilities erect permanent dikes around chemical tanks to confine spills in case the tanks leak and hazmat responders build temporary dikes around spills for the same reason. Topographical characteristics also affect the dispersion of a chemical release within the atmosphere. Hills and valleys are land features that channel the wind direction and increase wind speed at constriction points – for example, where a valley narrows and causes wind speed to increase due to a "funnel" effect. Forests and buildings are rough surfaces that increase turbulence in the wind field, causing greater vertical mixing that dilutes the chemical's concentration in the atmosphere. By contrast, water bodies are smooth surfaces that produce minimal wind turbulence, thus allowing the hazmat to maintain a high concentration at ground level where people inhale it.

The meteorological conditions of concern during a hazmat release are wind direction, wind speed, and atmospheric stability. The effect of wind speed on atmospheric dispersion can be seen in Fig. 1, which shows a release dispersing uniformly in all directions when there is no wind (Panel A). Thus, any plume isopleth (contour of constant chemical concentration) for this chemical is a circle. The nearby town lies outside the plume so its inhabitants would not need to take protective action. However, Panel B describes the situation in which there is a strong wind, so a plume isopleth for this case is an ellipse. In this case, the nearby town lies inside the plume so people there would need to take protective action.

As Table 1 indicates, atmospheric stability can vary from Class A through Class F. Class A, the most unstable condition, occurs during strong sunlight (e.g., midday) and light wind. This dilutes the released chemical by mixing it into a larger volume of air. Class F identifies the most stable atmospheric conditions, which take place during clear nighttime hours when there is a light wind. These conditions have very little vertical mixing, so the released chemical remains highly concentrated at ground level.

It is important to recognize that, at some times, meteorological characteristics can remain stable for many days but, at other times, can change from 1 h to the next. Figure 2, which Lindell et al. (2006) adapted from McKenna (2000), displays the wind direction at each hour during the day of the 1979 accident at the Three Mile Island nuclear power plant in terms of the orientation of an

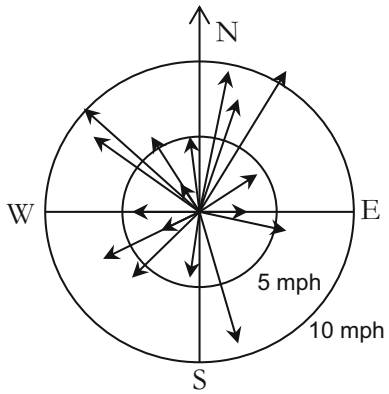


HAZMAT, Fig. 1 Effects of wind speed on plume dispersion. (From Lindell et al. 2006)

HAZMAT, Table 1 Atmospheric stability classes. (From FEMA/DOT/EPA n.d.)

	Strength of sunlight			Nighttime conditions	
Surface wind speed (mph)	**Strong**	**Moderate**	**Slight**	**Overcast ≥50%**	**Overcast <50%**
<4.5	A	A-B	B	–	–
4.5–6.7	A-B	B	C	E	F
6.7–11.2	B	B-C	C	D	E
11.2–13.4	C	C-D	D	D	D
>13.4	C	D	D	D	D

A: Extremely Unstable Conditions
B: Moderately Unstable Conditions
C: Slightly Unstable Conditions
D: Neutral Conditions (heavy overcast day or night)
E: Slightly Stable Conditions
F: Moderately Stable Conditions



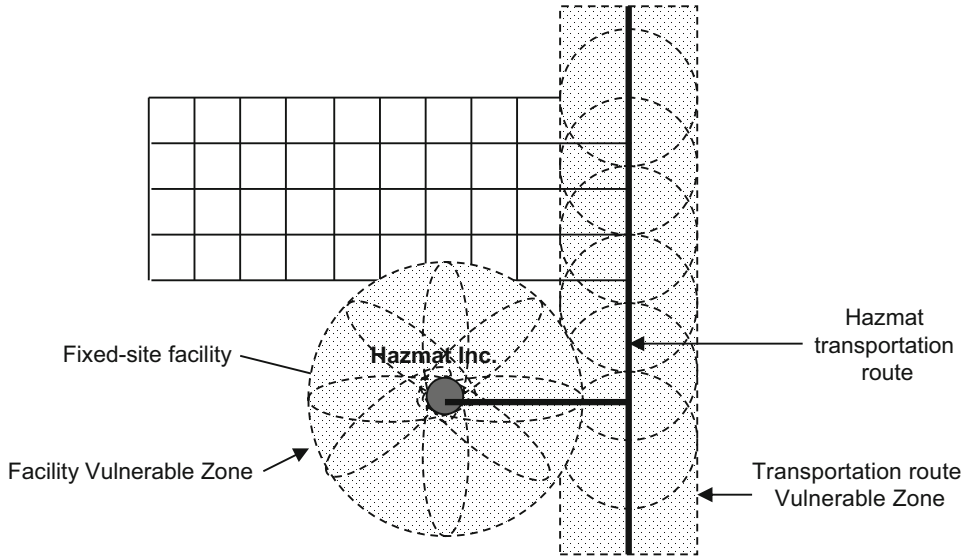
HAZMAT, Fig. 2 Wind Rose from 3 am to 6 pm on the 1st day of the 3 mile island nuclear power plant accident. (From Lindell et al. 2006)

arrow. Wind speed is indicated by the length of the arrow. The figure shows wind speed, and direction changed repeatedly during the course of the accident, so any recommendation to evacuate the area downwind from the plant would have referred to different geographic areas at different times during the day. This would have made evacuation notices extremely problematic because the time required to evacuate these areas would have taken many hours. Consequently, while the evacuation of one area was being implemented, the second order to evacuate in a very different direction would be issued, requiring simultaneous evacuations.

Hazmat Hazard Analysis: Fixed-Site Facilities

The process of identifying VZs around hazmat facilities begins by identifying dangerous chemicals (i.e., those that are threats because of their flammability, reactivity, or toxicity), their locations, and the quantities stored at those locations. Once the chemical inventory has been conducted, VZs can be computed using the data on the chemical's quantity available for release, the type of spill (liquid or gaseous), and the postulated release duration (e.g., 10 min) – all of which are combined to estimate the release rate. In addition, the VZ is defined by the chemical's toxicity, the assumed meteorological conditions (wind speed and atmospheric stability), and the terrain (urban or rural). Available methods for VZ computation are manual computations in the *Technical Guidance for Hazards Analysis* (USEPA 1987), desktop computations using *CAMEO/ALOHA* (FEMA, no date, see www.epa.gov/cameo), or online computations using *RMP*Comp* (www.epa.gov/rmp/rmpcomp).

Emergency planners can use the *Technical Guidance for Hazards Analysis* to calculate the size of the VZ for EHSs by identifying the number of pounds of hazmat in a tank or system of interconnected tanks (obtained from the facility operators) and the level of concern (LOC – the minimum concentration at which adverse health effects could occur – which is listed in an



HAZMAT, Fig. 3 Vulnerable zones around a fixed-site facility and transportation route. (From Lindell 2006)

appendix to the *Technical Guidance*). These data are used to enter one of four tables defined by the type of terrain (urban or rural) and atmospheric conditions at the time of the release (moderately stable or extremely stable). For example, the release of 800 lbs of chlorine (LOC = 0.0073) over a 10-min period from a water treatment plant located in a rural area during extremely stable atmospheric conditions and a wind speed of 3.4 mph (5.4 kph) would have a VZ radius of approximately 10 mi (16 km). If the plant were located in an urban area, the same scenario would result in a VZ radius of only about 1 mi (1.6 km) because the presence of buildings produces greater terrain roughness and, thus more vertical atmospheric mixing, than is found in rural areas.

Once the radii of the VZs for the different chemicals have been computed, these can be overlaid onto a map with the release point in the center of the circle and the radius drawn around it (see Fig. 3). The VZ around a fixed-site facility is a circle because a toxic chemical plume – which is usually elliptical in shape – could travel in any direction from the plant depending on wind direction. The VZs can then be used to identify areas within a jurisdiction that require hazard mitigation and emergency preparedness actions to protect the public health and safety, property, and the environment.

Hazmat Hazard Analysis: Transportation

Emergencies in hazmat transportation not only involve much smaller quantities of hazmat than at fixed-site facilities but, when they occur in populated areas, threaten local populations so quickly that emergency responders lack the time to perform the computations used for fixed-site facilities. Emergency planners should begin by identifying the highway, rail, water, and air routes through which hazardous materials are transported before an incident occurs. Once these routes have been identified, the number of tank trucks, railroad tank cars, and barges carrying each type of hazardous material can be counted in a *commodity flow study*. Information about hazardous materials transportation can be found on the DOT website (hazmat.dot.gov), and specific guidance for commodity flow studies is found at https://www.phmsa.dot.gov/technical-resources/hazmat-technical-resources/guidance-conducting-hazardous-materials-flow-studies. Once the

chemicals being transported have been identified, analysts can use the same procedures that were used for fixed-site facilities. A hazmat release can take place at any point along a transportation route, so its VZ is defined by a series of circles whose radius is calculated in the same way as for a fixed-site facility. Thus, the VZ for a transportation route forms a rectangle (see Fig. 3). The fixed-site facility and transportation route VZs can then be examined to identify areas of residential, commercial, and industrial land use (see Lindell et al. 2018, chapter 11, for an analysis of hazardous waste transportation to an incinerator).

If VZs for the transportation routes have not been identified before an incident occurs, local emergency responders need to search the incident scene for shipping papers, a numbered placard, or a placard with an orange numbered panel to obtain either the hazmat's name or its ID number so they can identify the correct section of the *Emergency Response Guidebook* (www.phmsa.dot.gov/hazmat/erg/erg2016-english). This document identifies these chemicals' potential hazards (fires, explosions, and toxic exposures), recommended response actions by firefighters and hazmat technicians, appropriate protective actions for emergency responders and the public, and recommended first aid measures for those who have received excessive exposures. For chemicals posing the greatest inhalation hazard, the *Emergency Response Guidebook* directs emergency responders to a Table of Initial Isolation and Protective Action Distances that should be used to select the appropriate protective action recommendations. These protective action distances are the equivalent of VZ radiuses for "small" and "large" spills during daytime and nighttime conditions. For a nighttime release of chlorine, the protective action distances would be 0.5 mi for a small release and 1.9 mi for a large release. Because the *Emergency Response Guidebook* classifies releases only as small or large, emergency planners should use the procedures in the *Technical Guidance for Hazards Analysis* or more advanced methods identified in the *Handbook of Chemical Hazard Analysis Procedures* wherever possible. In particular, the protective action distances in the *Emergency Response Guidebook* are *not* appropriate for use in computing VZs for fixed-site facilities.

Hazmat Hazard Analysis: Nuclear Power Plants

Exposure pathways for radiological materials are similar to those of toxic chemicals. Breathing air that is contaminated with radioactive materials can cause inhalation exposure, whereas eating food (e.g., unwashed local produce) or drinking liquids (e.g., water or milk) that is contaminated can cause ingestion exposure. Contamination also can enter the body through an open wound, such as a compound fracture, laceration, or abrasion, but radiological materials do not cause absorption exposures because they do not pass through the skin. However, because radiological materials release energy, they can produce exposures via direct radiation (also known as "shine") from a plume that is passing overhead. If the plume has a significant component of particulates, these might be deposited on the ground, vegetation, vehicles, or buildings, and the direct radiation from the deposited particulates would produce a continuing exposure. In this connection, it is important to recognize the distinction between irradiation and contamination. Irradiation involves the transmission of energy to a target that absorbs it, whereas contamination occurs when radioactive particles are deposited in a location within the body where they provide continuing irradiation.

The NRC conducted extensive analyses to define the emergency planning zones (EPZs) that should be designated around these facilities. These analyses led to the establishment of a 10-mile radius *plume inhalation EPZ* in which people might need to initiate protective actions to avoid inhalation exposure and direct radiation from a radioactive plume (NRC 1978). Protective actions within the 10-mile EPZ are expected to include sheltering, evacuation, and the use of potassium iodide. In addition, there is a 50-mile radius *ingestion pathway EPZ* in which authorities should prepare to monitor water, milk, and

food (especially leafy green vegetables) for contamination. Within the 50-mile radius, actions include bans on contaminated food and water (NRC 1980).

Conclusion

The *Emergency Response Guidebook* provides adequate guidance on the selection of protective actions for hazmat released during most transportation incidents. Such incidents can involve any one or more of a diverse set of chemicals, but the quantities tend to be small so protective actions are often – *but not always* – limited to the immediate vicinity of a release. However, incidents at fixed-site facilities can be much larger – sometimes affecting people 10 miles (16 km) or more downwind. Consequently, it is important for local emergency planners to know which facilities have hazmat and what are the quantities of hazmat that are stored at each facility. In addition, planners need to identify the VZs for each of the EHSs at these facilities and to develop emergency response plans that address protective actions such as evacuation or sheltering in-place.

Definition

Health security: the branch of security concerned with the impact of factors that threaten health and human safety on a societal and global scale.

Introduction

In 2020, scientists and researchers are working around the clock to understand the cause and transmission of the 2019 Novel Coronavirus (2019-nCoV, or COVID-19) after it was first detected in Wuhan City, China, in late 2019. Despite the focus on an emerging and rapidly evolving situation, little has been done to address the implications of the spread of the coronavirus on national security. The 2020 reactive response to identifying and isolating known and suspected infected individuals has not proven effective, with cases of the coronavirus reported worldwide. While some countries have closed borders and applied travel restrictions, there appears to be no systematic, rapid response approach to doing so. Furthermore, the methods of screening passengers at travel hubs, such as airports, do not appear to be effectively screening out those individuals that could pose a national security risk. This entry presents an overview of the history and epidemiology of COVID-19 and evaluates the initial response and management of this pandemic in an effort to evaluate US national preparedness and encourage improved response to prevent future pandemic events.

Coronavirus: History and Epidemiology

The 2019 Novel Coronavirus, a betacoronavirus similar to MERS-CoV (Middle East Respiratory Syndrome) and SARS-CoV (Severe Acute Respiratory Syndrome), was first detected in Wuhan City, Hubei Province, China, in late 2019. This infectious disease is transmitted from animal to human and from human to human. Despite the Centers for Disease Control and Prevention (CDC) stating that much is unknown about the initial transmission of the virus, there is speculation that the initial transmission of COVID-19 occurred at a Chinese market selling live and dead animals, and sources of the transmission (*vector*) may have been a bat, a pangolin, or another species in that open-air market (Achenbach 2020).

As of the first half of 2020, the CDC stated on its website that "limited information is available to characterize the spectrum of clinical illness associated with [2019-nCoV]. No vaccine or specific treatment is available. . .and care is supportive" (CDC 2020a). Individuals infected with COVID-19 are described as having "flu-like" symptoms similar to those of most viral infections (e.g., fever, coughing, chest pain, and general body aches). Because these symptoms are similar to the flu, they can easily be dismissed and/or overlooked. Another problem with identifying and diagnosing infected individuals with COVID-19 is that the symptoms exhibited by infected individuals can vary between patients. Moreover, some patients have no identifiable symptoms and prior to any strategies implemented to slow the infection rate, such as social distancing and/or masks, passed the disease to multiple people who in turn passed it to others. This issue, coupled with the purported two-week incubation period of the virus, has made it challenging to effectively contain the virus. Efforts continue to be underway

to better understand the history and epidemiology of the virus.

National Security: Isolating Individuals, Closing Borders, and Restricting Travel

The ultimate objective of responses to outbreaks is to contain infectious diseases (Maras 2014). Historically, this was achieved by isolating infected individuals and/or placing them in quarantine, closing borders, and restricting travel (see, e.g., responses to the Ebola Virus, Maras and Miranda 2015). Governments worldwide responded in a similar manner to COVID-19. These responses, isolation and quarantine, border closings, and travel restrictions, are permitted by national and international law (see Maras and Miranda 2015 for more information).

Isolation and Quarantine

In response to the pandemic, countries adopted isolation and quarantine measures for those who traveled to and from the Hubei Province in China and any individuals who were in contact and/or in close quarters with these travelers. These measures were subsequently also adopted for travelers from countries with high COVID-19 infection rates. As individuals arrived by air and sea, the United States opted to implement mandatory quarantines for the purported incubation period of COVID-19. While air travelers have been set up on land at quarantine facilities, sea travelers have been held offshore on cruise ships, unable to disembark. For example, in February and March 2020, several cruise ships were held off the coasts of the United States, Japan, and Hong Kong, establishing mandatory onboard quarantines, holding passengers on the ships, and confining them to their rooms for two weeks.

The CDC (2020b) published guidelines for dealing with individuals exhibiting COVID-19 symptoms. While the CDC recommends medical evaluation for high-risk individuals that are symptomatic, many of the actions proposed by the CDC in its guidelines are largely dependent on the individual and their desire to self-report or self-quarantine. Accordingly, the individual is self-driven to exercise restraint, report symptoms, and remain in isolation and quarantine for the duration of the incubation period. The reality is that individuals might not link their symptoms to COVID-19, report their symptoms, and implement/adhere to voluntary self-isolation or quarantine.

Border Closings and Travel Restrictions

Between January and June of 2020, several regions of the world opted to close their borders and impose travel restrictions on travelers from countries with high COVID-19 infections. As a border security measure, airports implemented exit and entrance screening methods in an effort to identify and isolate those individuals who are exhibiting symptoms consistent with COVID-19 infection. Airport entry and exit screening has included a mixture of traveler self-reporting and examinations by airport and airline staff. Self-reporting consists of passengers answering questions and/or filling out documents or travel cards concerning their travel history, contact history with infected individuals, and whether or not they have any "flu-like" symptoms (fever, cough, and general signs of illness). Screening methods conducted by airline and airport staff include general visual examinations looking for signs of illness and flu-like symptoms such as respiratory distress, coughing, and sneezing, along with the utilization of fever screening methods. Fever screening methods include the utilization of infrared thermometers (also referred to as infrared thermal scanners), which can be placed on the skin or in the ear. A more commonly used noncontact infrared thermometer does not involve human contact; instead, the thermometer is aimed at the passenger's forehead for rapid measurement of body temperature. These devices work by measuring body surface temperature and are different from contact thermometers that measure body core temperature (such as an oral thermometer). Surface temperature readings may not be as accurate as core temperature readings, because surface temperature is subject to acute environmental factors. Consequently, screening

with noncontact infrared detection systems may result in false positive and false negative results.

Several problems exist with border screening methods. First, the standards and methods for vetting passengers at the border, including policies of airlines and airports as well as the individual observational skills of airline employees and designated airport screeners, can vary. Second, the virus itself makes screening challenging since the incubation period makes it possible for infected individuals to travel before exhibiting symptoms and individuals may not exhibit the symptoms screeners look for. Third, the infrared thermometers are measuring surface temperature, so symptoms can be masked with fever medications (antipyretic). In one case, the news reported that a woman in France boasted on social media how she was able to evade airport screening in Wuhan and travel to France by taking fever-reducing medications to mask her "flu-like" symptoms (Mahbubani 2020). Finally, given that these procedures rely on self-reporting, people may not be truthful when answering questions or filling out the forms or they may not know if they were in contact with or in close proximity to an infected person. Even quarantined individuals being monitored present concerns. In January 2020, the news reported that an American attempted to flee a military base while being held for medical clearance after being evacuated from Wuhan, China (Jordan 2020).

Despite the subjectivity in screening methods and the variation in symptoms exhibited by infected individuals, visual screening and self-monitoring remain the two primary methods of preventing the spread of COVID-19. The rapid spread of the virus at the onset and the continued rise in cases into the second half of 2020 demonstrate that such measures may not be the most effective in maintaining national security. The implementation of universal travel and border control guidelines and more objective screening methods at the onset of a suspected outbreak, as well as the establishment of clear and consistent policies and procedures for quarantine and isolation, are needed.

Conclusion

Health security is an essential element of national security. Infectious diseases can destabilize nations due to their high death tolls and staggering economic, psychological, and social consequences. While the United States and other countries have responded to the COVID-19 outbreak with precautionary measures in the form of passenger isolation, travel restrictions, and border screening, these actions were not applied uniformly and therefore were not capable of preventing the spread of the virus domestically. Much is still unknown regarding the epidemiology and health impacts of COVID-19. The implementation of universal travel and border control guidelines and more objective screening methods at the onset of a suspected outbreak, as well as the establishment of clear and consistent policies and procedures for quarantine and isolation, are needed.

Homeland Security Act of 2002

James M. Duggan and James J. F. Forest
Center for Terrorism and Security Studies, University of Massachusetts Lowell, Lowell, MA, USA

Keywords
Department of Homeland Security · US Congressional Legislation · Federal Government · Terrorism · Counterterrorism

Definition

An Act passed by the Congress and signed into law by President George W. Bush creating the Department of Homeland Security and reorganizing several other government agencies.

Introduction

The attacks of September 11, 2001, created considerable fear among the US population and pressure for the government to punish those responsible for the attacks, as well as to better secure the homeland. The USA responded with a "war on terrorism" and the largest reorganization of the US government apparatus since the Central Intelligence Agency (CIA) and Department of Defense (DoD) were created in the wake of World War II (Crenshaw and Lafree 2017). President George W. Bush and his staff moved quickly to address the identified weaknesses and vulnerabilities within our counterterrorism structure, while some within the government made pleas for a more judicious approach to such an extensive reorganization (Chang 2014; Crenshaw and Lafree 2017). Nonetheless, the Homeland Security Act of 2002 (*the Act*) was quickly drafted and passed with overwhelming approval, effectively creating the Department of Homeland Security (DHS) and implementing a monumental restructuring of our nation's counterterrorism assets.

The Act and its creation of the DHS were intended to provide "...a single, unified homeland security structure that will improve protection against today's threats and be flexible enough to help meet the unknown threats of the future" (Bush 2002, p. 2). The Act enhanced the role of the Federal Emergency Management Agency (FEMA), making FEMA responsible for leading national emergency preparedness and response efforts, whereas FEMA had previously provided assistance, rather than leadership to state, local, and tribal agencies (Brattberg 2014). The Act tasked FEMA with the creation of a comprehensive response and recovery plan at the national level and served as the primary mechanism to administer an *all hazards* and whole of government approach to our national security efforts (Brattberg 2014). The Act created a comprehensive national security structure, addressing myriad concerns such as border and transportation security, cyber security, chemical, biological, radiological, and nuclear (CBRN) threats, and a unified information and intelligence component to formulate a comprehensive homeland security package (Bush 2002). This entry will briefly review the priority items within the Act and their importance to our homeland security. The Federal Emergency Management Agency, border security, and DHS will be covered in greater detail in other chapters within this volume entitled

► "Federal Emergency Management Agency", ► "Border Security", and ► "Department of Homeland Security (DHS)".

Definitions

Homeland security is officially defined by the *National Strategy for Homeland Security* as "a concerted national effort to prevent terrorist attacks within the United States, reduce America's vulnerability to terrorism, and minimize the damage and recover from attacks that do occur" (US Department of Homeland Security 2007, p. 3). Critical information and key resources (CIKR) are publically or privately controlled resources that are deemed essential to the minimal operations of the economy and government (Congress 2002). Some examples of the 16 critical infrastructure sectors are emergency services, financial services, energy, communications, and dams. Much of our CIKR within the USA are privately owned and managed, requiring collaboration with the private sector in order to assure minimal operations in the case of an emergency. Terrorists are criminals who commit or directly support acts of violence in order to achieve some type of sociopolitical objectives and are covered in more detail in the ► "Criminals: Terrorists" chapter within this volume.

Homeland Security Act of 2002

In the immediate aftermath of the September 11, 2001, terrorist attacks in New York City and Washington, DC, there was a great deal of public fear about the threat of future terrorist attacks and strong pressure for the Congress and the Bush administration to act quickly and decisively to address this threat. There was also no shortage of attempts to blame the attacks, and our perceived vulnerability to terrorism, on a variety of government agencies responsible for border security, transportation security, national security intelligence, and much more. On October 8, 2001, President Bush issued Executive Order 13228 creating an Office of Homeland Security within the White House and a Homeland Security Council, both having specific responsibilities for coordinating efforts against terrorism. However, some members of Congress felt a new federal agency, or full Cabinet-level department was needed in order to more comprehensively address the threat of terrorist attacks against the homeland. Just a few days later, Senators Joe Lieberman and Arlen Specter introduced legislation (Senate Bill 1534) to create a Department of Homeland Security. This legislation was debated for several months through various hearings and committee meetings, but never made it to the Senate floor for a formal vote.

On June 6, 2002, President Bush addressed the nation and proposed the creation of a permanent Cabinet-level Department of Homeland Security. Although the President of the USA may propose legislation, only the Congress can sponsor and pass the legislation necessary to create a new Cabinet-level department. On June 18 the White House submitted to the Congress a formal proposal to establish the DHS, along with proposed text for what became the Homeland Security Act of 2002. On June 24, Rep. Dick Armey sponsored the proposal for introduction to the House of Representatives as H.R. 5005. After amendments in committees, the bill was passed on July 26, 2002, by a vote of 295 to 132. Then the Senate spent several months debating and amending the legislation, which was finally passed by a vote of 90 to 9 on November 19, 2002.

The Act was signed into law by President Bush on November 25, 2002, and presented sweeping changes to our homeland security efforts. The Act established the DHS and merged responsibility for critical issues of homeland security under one umbrella (Brattberg 2014). DHS became responsible for the protection of CIKR, emergency preparedness, and the sharing of information among federal, state, local, and tribal agencies (Brattberg 2014). More specifically, the Act declared the primary mission of DHS to include the following: (1) prevent terrorist attacks within the USA; (2) reduce the vulnerability of the USA to attack; (3) minimize the damage from and assist in the speedy recovery from a successful attack; (4) act as a "focal point" for natural, as well as man-made disasters, and for the emergency planning relative

to those events; (5) identify and disrupt connections between illegal drug trafficking and terrorism; and (6) assure that the efforts of DHS to secure the homeland do not negatively impact the economic security of the USA (Congress 2002).

The Act also transferred 22 existing federal offices into DHS, with the intent of consolidating agencies with a responsibility for homeland security under one umbrella (Brattberg 2014). Among the more noteworthy agency offices that were transferred into DHS were the US Customs Service, the Federal Protective Service (which provides police services at federal buildings), the Transportation Security Administration (TSA), the Federal Law Enforcement Training Center, the Federal Emergency Management Agency (FEMA), the US Secret Service, and the US Coast Guard (Crenshaw and LaFree 2017).

Because the threat was viewed as originating from outside the USA, border security was afforded considerable attention (Crenshaw and LaFree 2017). The Act established the Directorate of Border and Transportation Security, which assumed control of several transferred departments and agencies. The Immigration and Naturalization Service (INS) and the US Customs Service were transferred under the control of the Directorate of Border and Transportation Security, with INS to be abolished upon completion of record transfers (Congress 2002). The Directorate of Border and Transportation Security divided the duties of INS and US Customs between three new departments: the Bureau of Customs and Border Protection, the Bureau of Citizenship and Immigration Services, and the Bureau of Immigration and Customs Enforcement (ICE) (Congress 2002). In turn, ICE absorbed the Federal Protective Service (FPS) and US Customs Service to form the largest investigative agency within DHS (Crenshaw 2017). ICE was entrusted with the duty to protect the country's borders from penetration by terrorist actors, as well as weapons and weapon components (Crenshaw 2017). In addition, the Act established a program that would allow volunteer pilots to be armed and deputized as federal law enforcement officers (Congress 2002).

The Act also established a Directorate for Information and Analysis (I&A) within DHS that was charged with the duty of providing information and intelligence in support of DHS (Brattberg 2014). DHS I&A was expected to accomplish this mission by collaborating with state and local agencies, as well as the private sector, to identify and assess terrorist threats to the homeland within the context of vulnerabilities previously identified by I&A (Congress 2002). In addition, I&A was required to develop a national plan to protect our CIKR by first conducting vulnerability assessments followed by the creation of a plan to protect not only the physical assets of our CIKR but also the technologies required to support the resiliency of those resources (Congress 2002). The Act also entrusted DHS I&A with the daunting task of developing policies for improving the sharing of information and intelligence among federal agencies, as well as between the federal, state, local, and tribal agencies (Congress 2002). DHS was later relieved of this task with the creation of the Office of the Director of National Intelligence on 2004.

With the implementation of the Act, FEMA took the lead in training, planning, and coordinating with state and local agencies to prepare for the response and recovery from man-made (terrorist) as well as natural disasters (Bush 2002). Prior to implementation of the Act, the federal government had primarily assisted state and local agencies by augmenting their equipment and personnel resources in the case of a large-scale natural disaster (Brattberg 2014). DHS' new planning and response capabilities included the ability and responsibility to detect and counter chemical, biological, radiological, and nuclear (CBRN) threats. In addition, DHS was tasked with developing a national interagency response and communication plan, which would lead to the development of the National Incident Management System (NIMS). The Department of Health and Human Services (HHS) was also transferred to DHS, despite warnings against the transfer because of lack of congruency between the missions of the two agencies (Rittgers 2014). DHS therefore assumed the HHS responsibility

for maintaining a stockpile of pharmaceutical drugs that would be necessary in the case of assorted disasters and assumed the obligation of managing grant funding to assist state and local first responders (Congress 2002).

Conclusion

The creation of the DHS has been criticized by some for being too rushed, a hasty reaction to a politically charged environment in which the threat of terrorism may have been exaggerated. Of course, even with meticulous planning, such a massive restructuring of government agencies could be expected to be rife with pitfalls, but the expeditious implementation of the Act and launching of DHS all but assured those pitfalls (Rittgers 2014). Virtually no American citizen has been unaffected by the sweeping changes in security policies that have emerged in the years following the passage of the Homeland Security Act of 2002. But despite criticisms, the survival of the DHS was recently assured with the DHS Authorization Act of 2017, which committed the USA to improving the weaknesses within DHS by consolidating programs, controlling spending, and providing greater support to state and local first responders, rather than initiating a superseding reorganization of our homeland security agencies (Congress 2017).

Human-Made Disasters: Electric Power and Transit Linked Outages

Rae Zimmerman
Institute for Civil Infrastructure Systems, Robert F. Wagner Graduate School of Public Service, New York University, New York, NY, USA

Keywords

Electric power · Rail transit · Infrastructure interdependencies · Power outages · Natural hazards · Human unintentional and intentional actions

Definition

Electric power outages related to transit service continuity are associated with a number of factors that originate in transit and electric power system characteristics, such as the capacity to withstand equipment issues; environmental conditions, including natural hazards, such as extreme weather and climate change impacts on energy systems (U.S. DOE 2013a) and human responses to those conditions; unintentional human actions, such as the accidental, inadvertent disruption of a power line or street salting; and intentional human acts, such as sabotage and cyberattacks (Zimmerman 2012a, Chapter 7; Zimmerman 2017).

Introduction

The scope of electric power and transit linkages in this entry signifies connections between electric power and rail transit systems primarily to move transit vehicles that provide vital transportation services. Electric power is also used for supporting facilities such as signals, switches, lighting for rail, vehicles, and stations and for cleaning and servicing equipment; however, the electric power linkages to these functions are not within the scope of this entry. There are many different forms of transit, and this entry focuses on public rail transit as distinct from buses and paratransit. Within the category of rail transit, the focus is on heavy rail, since in the USA according to the National Transit Database (NTD) (US Department of Transportation (DOT), Federal Transit Administration (FTA), NTD, 2018a), heavy rail accounts for a large part of the services and activity relative to all transit systems. According to calculations from the NTD, heavy rail accounts for among the highest levels of passenger travel in terms of trips, which is a little over a third of passenger trips, and about a third of all passenger miles traveled (U.S. DOT, FTA, NTD 2018a). Heavy rail passenger trips also were reported by U.S. DOT, FTA, NTD, Office of Budget and Policy (2019a: 21) to have increased by 6.7% from 2009 to 2018. Heavy rail accounted for half of all rail security incidents in the period from 2009 to 2018, and two-thirds of those were related to security, most occurring at train stations (U.S. DOT, FTA, NTD, Office of Budget and Policy 2019b, p. 21). Heavy rail ranks high in annual energy use among other transit systems (U.S. DOT, FTA, NTD 2018b, Fuel and energy_2.xlsm).

Electric power is important for transit performance since energy is one of transit's essential resources. The transition of rail systems to electric power occurred over a period of a few decades following the introduction of rail transit. The extent of rail transit energy usage and electric power outages and the impact of such outages on transit are key aspects of the viability of public transportation. This entry covers these issues for heavy rail transit.

Heavy Rail Transit in the USA

Heavy rail is defined by the National Transit Database (NTD) (U.S. DOT, FTA, NTD, Glossary 2020, pp. 32–33): "A transit mode that is an electric railway with the capacity for a heavy volume of traffic. It is characterized by: – High speed and rapid acceleration passenger rail cars operating singly or in multi-car trains on fixed rails – Separate rights-of-way (ROW) from which all other vehicular and foot traffic are excluded – Sophisticated signaling – High raised platform loading."

The US Department of Transportation (DOT) Federal Transit Administration (FTA) NTD (2018a) lists 15 heavy rail transit systems in the USA. Together, these systems accounted for 3,724,442,285 unlinked passenger trips in 2018 exceeded by bus transit which was close to 4 billion trips (U.S. DOT, FTA, NTD 2018a, NTD data, 2018 Metrics). The largest of these systems is the Metropolitan Transportation Authority (MTA) New York City Transit system which in 2018 served a US Bureau of the Census-defined urbanized area (U.S. DOT, FTA, NTD 2020, Glossary) of over 18 million people; accounted

for 2.7 billion annual unlinked passenger trips which is about ten times the passenger trips for the second and third largest heavy rail systems; and accounted for about 70% of US heavy rail unlinked passenger trips and about 60% of passenger miles (calculations from the U.S. DOT, FTA, NTD 2018a, NTD data, 2018 Metrics). Given its size, the NYS MTA will be emphasized in the presentation of electric power and transit linkages.

The reliance of heavy rail on electric power is underscored by the NTD (U.S. DOT, FTA, NTD 2019b, p. 3):

"Heavy Rail (HR) is an electric railway that operates service in an exclusive right-of-way." (U.S. DOT, FTA, NTD, Office of Budget and Policy 2019b, p. 3). The NTD indicates that other transit systems run on electric power as well, but heavy rail seems to consume more electric power (U.S. DOT, FTA, NTD (2018b) 2017 Fuel and Energy_2.xlms). Electric power consumption is reported by the NTD as "electric propulsion" defined as "kilowatt-hours of electricity used to propel vehicles directly providing power to a third rail or overhead catenary" (U.S. DOT, FTA, NTD (2018b) 2017 Fuel and Energy_2.xlsm Data Dictionary). In 2017, the electric propulsion for the 15 heavy rail transit systems in the USA totaled 3,728,009,564 kWh (U.S. DOT, FTA, NTD (2018b) 2017 Fuel and Energy_2.xlsm), or 56% of the total electric propulsion reported for all transit systems totaling 6,604,153,364 kWh (not only rail transit). NYC Transit consumed 1,624,428,000 kWh in terms of electric propulsion, which was a quarter of the 6,604,153,364 kWh for all US transit systems and 44% of the 15 heavy rail transit system consumption of electric propulsion of 3,728,009,564 kWh (U.S. DOT, FTA, NTD 2018b, 2017 Fuel and Energy_2.xlsm).

The History of Rail Transit and Its Energy Sources

The connection between electric power and rail transit increased over time following the introduction of the first rail transit systems. The first rail transit systems were the London Underground subway in 1863 transporting 40,000 people in the first day of operation and the Boston, MA, subway which opened in 1897 consisting of 3 stations under 1 mile in length (HERE Mobility 2019, p. 11 citing Coldwell 2013 for London and Brooks 2017 for Boston). In the nineteenth century, rail travel relied on wood for power, then coal to produce steam, and diesel. As described by Lothes (2009), the electrification of the first rail system is said to date back to 1895; by 1939 the USA accounted for a fifth of the world total.

In addition to heavy rail transit systems reported by the NTD, other heavy rail systems have substantial reliance on electric power. Amtrak's use of electric power for train energy consumption generally was reported as increasing from 1975 to 2008 (180 million kWh to 582 million kWh), decreasing thereafter through 2015 to 504 million kWh, and increasing to 516 million kWh in 2016 (U.S. DOT, Bureau of Transportation Statistics, 2019, Table 4–18). Amtrak (2018, p. 12) indicates that electricity ranks second to diesel fuel for energy consumption and estimates that about three quarters of the electricity is used for trains with the rest for other uses.

New York City subways were converted to electric power at the turn of the twentieth century, with the banning of steam-driven commuter railroads by 1908 south of the Harlem River, and the transition was attributed to an accident on January 8, 1902, involving steam-powered trains that obscured signals (Horn 2015; NYSDOT undated; Lothes 2009). In the New York area rail transit system, the New York Metropolitan Transportation Authority (MTA) exemplifies how the relationship of one of its components, the subway system (New York City Transit), changed over time in terms of its electric power providers. NYC once had its own electric power substations, 75 of them, most of which were built in the early twentieth century (Payne 2002, p. 31). They received electric power from power stations, converting the power from alternating current (AC) to direct current (DC), lowering voltage for distribution of power to the third rail, and

considered one of the last such "manually operated" systems (Payne 2002, p. 12). In 1959, Con Edison bought several of the MTA power plants in return for Con Edison agreeing to provide the subway system with electric power (Payne 2002, p. 53).

The NYC subway transitioned initially from steam to electricity and then to diesel with electricity continuing to dominate the power sources. In the late nineteenth century when the first rapid transit systems emerged in NYC, they relied upon steam-powered locomotives (Payne 2002, p. 15). Electrification of rail is attributed first to have occurred for overhead electrical lines in Richmond, VA, in 1888, followed by the electrification of Chicago's third rail in 1895, with New York City following with electrification of its elevated train lines from 1898 to 1903 (Payne 2002, p. 15). In the twenty-first century, newer sources of electricity emerged such as solar energy described later, applied to rail transit, primarily as a power source for stations. Diesel locomotives continue to be used for emergency purposes, for example, by the NYS MTA, either to move stalled trains or to provide limited service on disabled lines, and were used, in September–October 2013 for the New Haven Line power failure (Flegenheimer 2013). Diesel-powered generators are increasingly relied upon for emergencies with new generators purchased, for example, for the MTA LIRR (MTA 2019a, p. 39).

Electric power is distributed to the NYC subway system by Con Edison; power sources include the New York Power Authority (MTA Undated (a), pp. 5, 13) and others (Con Edison 2019a, b). Electric power sources for the NYC subway system vary depending upon the system component. The third rail runs on one type of power, and the signals and lighting run on another source. The MTA reports that by type of power "Alternating current (AC) operates signals, station and tunnel lighting, ventilation, and miscellaneous line equipment and Direct current (DC) operates trains and auxiliary equipment, such as water pumps and emergency lighting." "Substations receive as much as 27,000 volts from power plants and convert it for use in the subway. The third (contact) rail uses 625 volts to operate trains" (MTA undated (b), p. 4).

Impacts of Electric Power Outages for Transit

Electric power outages in the USA have generally increased in terms of frequency and duration (Simonoff et al. 2007), which are the common measures of electricity performance. With respect to system reliability, the NYS Department of Public Service (DPS) (2019, p. 1 and footnote 1) has adopted these two measures typically used in the industry for frequency and duration of outages: "the System Average Interruption Frequency Index (SAIFI or frequency) and the Customer Average Interruption Duration Index (CAIDI or duration)" defined in the following way: "SAIFI is the average number of times that a customer is interrupted for five minutes or more during a year. CAIDI is the average interruption duration time in hours for those customers that experience an interruption during the year." These measures and similar ones are applied to urban areas (Blake et al. 2019; National Academies of Sciences, Engineering and Medicine 2016a). Electric power outages are generally related to a number of factors associated with system characteristics and environmental conditions that vary for underground and overhead electric power lines. As indicated above in the definition, these factors include natural hazards such as extreme weather and climate change (U.S. DOE 2013a); equipment malfunctions; unintentional human actions such as the accidental, inadvertent disruption of a power line or street salting; and intentional human acts such as sabotage and cyberattacks (Zimmerman 2012a, Chapter 7; Zimmerman 2017).

Electric power outages are a source of transit outages though not the only source of such outages as indicated above. Heavy rail transit systems are typically connected to electric power grids and as such are vulnerable to outages that affect the power. In addition, when power is restored, it can take additional time for the transit systems to be

restored (Zimmerman and Restrepo 2006) given the multiplier effect created by the need for adjustments and inspections before the systems are put back in service. After Hurricane Sandy, heavy rail train service was not fully restored for a week or more after the storm; The NYC subway system and other heavy rail lines such as the PATH had pumped out much of the water but had to await power restoration to restart the system (NYS 2100 Commission 2013, p. 45; Kaufman et al. 2012; Zimmerman 2014; Zimmerman 2016). Major hurricanes have resulted in extensive power outages that often have long restoration times (Miles et al. 2014, 2015; U.S. Department of Energy 2013a, p. 2; 2013b), and these cases have been recognized in research on infrastructure interdependencies (Zimmerman et al. 2017; Zimmerman 2020 forthcoming). Many of these power outages have been associated with transit outages. Although extreme weather is a natural hazard, the extent of the consequences is often affected by human activity (National Academy of Sciences 2016b).

Transit has been shown to be vulnerable to power outages in large outages that are not weather-related, and as in the case of weather-related outages, the effects can be magnified by the duration of recovery. Zimmerman and Restrepo (2006, p. 223) reported that after the 2003 US-Canada blackout, for example, NYC transit systems took 1.3 times longer to be restored than the time it took for the power itself to be restored. A massive electric power outage in London on August 9, 2019, created extensive transit delays before service was restored, and though it took under an hour for power restoration, transit services were not restored until the next day (Karasz 2019). In Buenos Aires and neighboring parts of Uruguay, a power outage in June 2019 specifically disabled the transit system (Trevisani and Lewis 2019). A massive disruption created by the disabling of 135,000 kV power lines for the MTA Metro-North system lasted weeks after the voltage problem was restored at least temporarily (Flegenheimer 2013; MTA 2014).

For New York City, the NYS Governor has attributed numerous delays in subway service to power (French and Rubinstein November 21, 2017, Paragraph 2). In April 2017 the system experienced damage to a 53rd Street and 7th Avenue energy system resulting in cascading failures of numerous subway lines (French and Rubinstein 2017). Power failures occurred again on May 7, 2019, and in July 2019, some of which affected transit.

Unintentional acts that lead to power outages include equipment disruptions, for example, from 2016 and 2019, a number of high-profile outages were accompanied by transit stoppages in New York City. Intentional acts such as terrorism have disrupted heavy rail systems either directly, or service has been disrupted indirectly by preemptive shutdowns in anticipation of such events. Both of these situations occurred in NYC after the World Trade Center attacks of September 11, 2001.

In New York State, extreme weather events were separated from non-weather-related phenomena in connection with electric power outages. The NYS Department of Public Service (2019, p. 7) concluded that excluding storms, most of the outages were attributed to "equipment failure and tree contact." From March through May of 2018, the department identified five major storms that add to a total of 1.136 million outages (some statewide, some regional), and the duration of the outages sometimes exceeded 3 days (NYS Department of Public Service 2019, pp. 9–10).

Innovations to Improve Resilience for Both Electric Power and Transit

Innovations in the use of electric power are emerging that have the potential to reduce electric power impacts for rail and promote sustainability (Abdallah 2017, pp. 61–65). Many of these are technological. Regenerative braking is one way to conserve electric power by enabling the train system to use its own power. The NYS MTA (MTA Undated (a), p. 13) describes the use of regenerative braking in its "New Technologies subway cars (also called New Millennium Trains)"

models R-142, R-142A, R-143, and R-160 on selected subway lines where energy normally lost as heat is returned to the third rail through regenerative braking. Some of the conditions of using this technology are the timing of the generation and its transfer to another train (González-Gil et al. 2013). Storage systems have been explored in some heavy rail transit systems to enable such transfers to occur (Chicago Transit Authority (CTA) and Mott MacDonald 2017).

Other options are changing the material used for the third rail to reduce the amount of energy lost, for example, "Since aluminum is a better conductor of electricity than steel, NYC Transit is experimenting with two kinds of aluminum third rails to save energy: an all-aluminum rail with a stainless steel cap on its contact surface; and a steel-and-aluminum hybrid rail that has a steel base and aluminum cladding on its sides. Aluminum is also lighter than steel, which means aluminum-component rails are easier to handle, install, and replace than conventional steel rails" (MTA Undated (a), p. 13).

Another technology is called the "Subway Car Shunting Elimination Program" that began in 1996, considered "one of its most successful energy conservation projects. By modulating the acceleration rate and limiting the top speed of the 5,800-car subway fleet, NYC Transit reduces energy use per subway car mile by 12 percent and saves 240 million-kilowatt hours of electricity annually" (MTA Undated (a), p. 13).

Increased use of renewable energy is an option but also relies upon storage. The Coney Island Stillwell station is an important example of the use of solar energy for station lighting and other support systems. Other rail transit systems are similarly tapping solar energy, for example, Boston's T line uses solar energy primarily for support facilities such as parking, rail yards, and garages (Massachusetts Bay Transportation Authority (MBTA) undated). It is not certain what the extent of solar power usage is to power trains directly unless it is used indirectly by sources tapped for electric power in general. Energy storage systems, wayside energy storage system (WESS), are being considered for transit systems to save on energy use through voltage stabilization (Abdallah 2017). Chicago is an illustration of the introduction of this technology into transit (Chicago Transit Authority and Mott MacDonald 2017).

Energy conservation in general is potentially a way to protect against the vulnerability of electric power outages. Energy intensity reflects energy conservation, measured in terms of Btu per passenger mile, and varied in 2016 for US heavy rail systems from about 500 to 3250 Btu per passenger mile; New York ranked second lowest with a little over 500 Btu per passenger mile (Davis and Boundy 2019, p. 2–22).

Other options for potentially promoting resilience in electric power systems for transit relate to electric power alone (Con Edison et al. 2013; Con Edison 2017a) and for transit alone (MTA 2016; MTA 2019b) which tend to be operational. For example, with respect to NYC Transit, on August 2, 2017, Con Edison (2017b) issued a statement indicating its approach to reducing the impact of power outages on the subway system in response to the NYS Public Service Commission (Con Edison 2017b, Paragraph 2).

Resiliency options involving transit alone have been addressed separately by the MTA in connection with extreme events and climate change (Jacob et al. 2008; Zimmerman 2012b; Jacobs et al. 2018; MTA 2019b; Zimmerman et al. 2019).

Observations and Conclusions

Electric power outages pose a key vulnerability to public transit and particularly to heavy rail transit, which is the focus of this inquiry. Power-related transit conditions are reflected in the apparent increase in the number of power outages and the effect on transit. This is a significant problem given the substantial ridership these systems account for and the need to reduce vulnerability to those populations and promote resiliency and sustainability that transit systems offer. As newer technologies emerge and may potentially be applied to rail transit, such as autonomous vehicles, the impact upon electric power usage will need to be evaluated along with the implications of power outages to those technologies.

Ways of reducing this vulnerability are emerging and are potential solutions for electric power and transit. Making progress toward this goal will require attention on the part of both of these systems simultaneously and the recognition of the dependency of transit on electric power to move toward solutions. Electric power and transit will have to come together in terms of technology, social, and environmental impacts, and the institutions overseeing them will play a major part in the integration of these two systems.

Toxic Waste · Flint · MI · Love Canal · Environmental Justice

Definition

The issue of toxic waste and residences includes incidents and policies related to the broader environmental justice and antitoxic movements in the United States, including "NIMBY" (Not In My Backyard), health effects, and considerations of environmental racism.

Introduction

On the South Side of Chicago lies a federal housing project, originally created for African-American veterans. Nicknamed the "toxic doughnut," it has the highest concentration of hazardous waste sites in the nation, being surrounded by 50 landfills and 382 industrial facilities, with 250 leaking storage tanks underground (Cosier 2017). Studies have revealed dangerous levels of toxic chemicals in the area, with the community having the highest cancer rates in the city (Cosier 2017; Taylor 2000; Wenzel 1998). Since industrialization began in modern America, we have seen issues of toxic waste and how it affects communities unfold repeatedly. With the inception of the antitoxic and environmental justice movements, communities have and continue to grapple with issues of toxic waste near their homes and the consequences of such environmental hazards.

Love Canal: The Beginning of the Antitoxic Movement

The toxic waste disaster at Love Canal in the late 1970s garnered attention and galvanized grassroots environmental justice movements. Between 1942 and 1953, Hooker Chemical Corporation filled a canal with 21,800 t of chemical waste in the city of Niagara Falls, New York. Despite this, the site was later sold to the Niagara Falls school board for one dollar and included a deed with a provision that relieved Hooker Chemical of any future liability. Years later, after the drums of chemicals had gradually corroded, the contents leached through the soil into the basements and backyards (Levine 1982). Residents had complained of strong odors and substances around their homes for years prior. Children had complained of burning feet while barefoot in their yards, along with unexplained skin irritations (Silveira 2000). After a winter storm in 1977, with a rising water table, the toxic waste flowed out into the backyards of residents. By the time citizens were aware of the threat of chemicals, serious consequences had potentially already occurred (Levine 1982). By 1978, this was national news and considered a disastrous environmental tragedy.

Members of the community took action, led by Lois Gibbs of the Love Canal Homeowners Association. Gibbs' son had respiratory problems after attending the school built on top of a toxic waste disposal (Silveira 2000). Frustration with government officials was paramount as the community protested, alleging that the Niagara County Health Department and other officials had known about the problems in Love Canal and ignored them. The residents of the association developed a community health survey, confronted politicians, and protested (Silveira 2000). It was eventually recommended that pregnant women and children under the age of 2 relocate. In the end, the federal government bought out the homes of hundreds of families and the residents left.

Ultimately, Love Canal became a catalyst for the antitoxic movement, as well as the creation of the Superfund through the Environmental Protection Agency, which is a program to fund the cleanup of the most contaminated and toxic sites in the country. Prior to this incident, toxic waste was not an issue seen as a serious threat to communities. This changed after Love Canal. By 1980, America feared toxic waste just as much as they had feared nuclear power after the Three Mile Island meltdown, and concerns about toxics led to the development of social movement organizations (Szasz 1994).

The antitoxic groups developed underneath the broad definition of the environmental movement, concerned with the effects that waste have on people, including their own families. Initially considered a movement of housewives, motivated women with little political knowledge became

activists (Silveira 2000). As the movement grew, the government eventually established the Center for Health, Environment, and Justice (formerly known as Citizen's Clearinghouse for Hazardous Wastes) in 1981.

This event, like many others, began as a "Not In My Backyard" problem – otherwise called "NIMBY." These groups are locally formed antitoxics groups created in reaction to perceived local health risks to families and communities (Silveira 2000). Residents were troubled by the public health repercussions from possible groundwater contamination, especially since this occurred in the aftermath of Love Canal (McGurty 1997). It eventually became apparent that toxic waste could threaten everyone; it was always a present danger (McGurty 1997).

The National Toxics Campaign and other social organizations were created to address the issue in people's backyards that was gaining attention. Critics were quick to label many involved with these organizations as NIMBYs, who were not concerned about where the toxic waste ended up as long as it was not near them. This was largely a sweeping that did not apply to the vast majority of those in the movement who did indeed push for the reduction of toxic waste everywhere. By the 1980s, social justice-oriented movements were becoming enmeshed with environmental causes, ultimately leading to the concept of environmental justice.

The Environmental Movement

The modern environmental movement began after Rachel Carson's publication of *Silent Spring* (1962), which focused on toxics harming the environment and wildlife. Prior to this time, the environmental movement was primarily concerned with conservation. Gunter and Kroll-Smith (2007) identified the three prominent types of environmental conflict as conservancy disputes, siting disputes, and exposure disputes. Conservancy disputes are struggles over how to define and protect natural areas and species. Siting disputes characterize what happens when conflict arises over some proposed land use, and exposure disputes involve fights against hazards already present in a community. Siting and exposure disputes are particularly salient where toxic waste is concerned.

The environmental justice movement has adopted a model of science as embedded in social structures. Environmental conflicts arise when a community exposed to a hazard makes connections between their health and the hazard in their community (Hannigan 2006). Allen (2003) describes this with a particular scenario on popular epidemiology. A woman by the name of Robinson established a health registry in her Louisiana community, making maps to track various illnesses and their proximity to Superfund sites and chemical industries to prove causation. This is a heavily contested issue in environmental movements, because causation tends to be ambiguous and extremely difficult to prove. Indeed, public health has become a major concern, as have efforts to hold hazardous chemical sites and corporations accountable.

The environmental justice frame was built around a concept of rights constructed by the rhetoric of previous social movements (Čapek 1993). Four major components of the environmental justice discourse were identified by Čapek (1993). All citizens have a right to obtain accurate information about the situation, a serious unbiased hearing when contamination claims are made, democratic participation in deciding the future of the community that has been contaminated, and compensation from those who have inflicted harm and polluted a community (Čapek 1993; Hannigan 2006). The concentration and dependence on the legal system to compensate victims of environmental wrongdoings and to hold accountable those who committed those wrongdoings are built into the framework for environmental justice movements.

Additionally, the environmental justice movement has a framework for social change that includes the principles that all individuals have the right to be protected from environmental hazards and degradation. It also adopts a public health model of prevention which focuses on the elimination of a threat before the harm occurs, shifts burden of proof to the polluters, and redresses

disproportionate risk burdens (Brulle and Pellow 2006). This is in line with the precautionary principle, which means that rather than presuming possible hazards are safe until data proves otherwise would mean allowing scientific uncertainty to delay action, so the burden is shifted to instead show an actual absence of harm (Brulle and Pellow 2006; Hannigan 2006).

We can look to the example of grievances and environmental justice as described by Čapek (1993) and his case study of the Carver Terrace neighborhood in Texas. The grievances that led to this environmental movement in the community began with health problems, which residents claimed were the result of contamination in their neighborhood by the corporation Koppers Texarkana. This led to more people becoming involved and turning to the judicial system for justice. Their claims were considered valid, as the Environmental Protection Agency had become aware of the problem many years prior, and declared Koppers Texarkana a Superfund site (Čapek 1993).

Illnesses related to environmental hazards can lay dormant for years. This is why some argue we have yet to see the full effect of toxic waste on public health (Brulle and Pellow 2006). With the passage of the Superfund Act and the 1986 Emergency Planning and Community Right-to-Know Act, the movement gained momentum for using government funds to clean up hazardous sites and give citizens more power.

The Chemical Corridor

The civil rights movement of the 1960s and the environmental movement of the 1970s ushered in the era of environmental justice in the 1980s, particularly in poor and minority communities that recognized the disproportionate amount of hazardous waste located where they lived (Allen 2003). In 1989 the environmental justice movement gained momentum in Louisiana, when residents organized the first Great Louisiana Toxics March to bring attention to the illnesses and industrial pollution in their communities, located within the chemical corridor (Allen 2003). The commercial development of this area was ushered in by the wealthy few with power and the enticing corporate-friendly environment by a government that required no property taxes and was near a water supply – the great Mississippi River. This area is home to many chemical corporations and involves both siting and exposure conflicts (Allen 2003). Though called the Chemical Corridor by many, to others it is known as Cancer Alley, or Death Alley, representing a range of fatal illnesses that struck the communities along the river. Other signs of powerlessness are ever present. Loudspeakers are posted on telephone poles to sound alarms and warn residents in the event of a chemical leak.

In Louisiana, companies had to apply for separate permits based on whether it polluted the air, water, or ground. This three-media permit system allowed corporations to creatively hide pollution and toxics (Allen 2003). At public hearings for permits regarding toxic waste, resident concern and questions were only fielded if they addressed the permit application directly (Allen 2003).

The work of expert-activists became essential to the Louisiana movement. Expert-activists inform residents of the scientific knowledge, laws, and regulations related to their rights with regard to environmental issues. These individuals became teachers for the residents to help them explain their experiences in ways that would help them gain legitimacy in public policy. The citizens needed to have a basic understanding of toxic waste and its effects, and they needed to understand the process by which they might initiate change. The production and distribution of information was an important goal. One community group – Save Our Selves – filed a lawsuit again the Louisiana environmental control commission and the Department of Natural Resources and, eventually, won (Allen 2003). The state supreme court decided that citizens' environmental protections must be considered equally with economic and social factors. After this, corporations wanting to site their facility in the corridor had to demonstrate that they had considered alternative sites and proposed the most advanced pollution control processes to mitigate harms. While toxic waste would still be some concern, the

benefit of economics and jobs would remain in this "industrial corridor," so-called by government officials attempting to emphasize economic advantages for citizens. These advantages are misleading, because the jobs require specific skill sets that unskilled workers cannot occupy. For the state, the chemical corporations exemplify a capital investment.

Environmental Racism and Siting of Toxic Facilities

In Warren County, North Carolina, an environmental hazard was brewing in 1982, leading to the first large-scale civil disobedience within the environmental justice movement. Warren County was a predominately African-American community selected for a landfill to dump PCB-contaminated waste. When residents became aware, they blocked the trucks from entering the site. Ultimately, this drew attention to how environmental toxics affected minority communities, and environmental racism began to gain attention.

Bullard (1990) defined environmental justice as the principle that all people and communities are entitled to equal protection under environmental and public health regulations. Bullard used this frame in his work *Dumping in Dixie*, which examined five communities in the South and the activism and mobilization strategies of black residents who were confronted with environmental hazards. In each of the states where Bullard researched case studies, the population of black residents was around 30%. However, in communities where hazardous waste and dumping sites were found, the black and minority population was at least 90% (Bullard 1990). Bullard's work became the first in-depth study of environmental racism. Environmental racism refers to discrimination in environmental policymaking (Brulle and Pellow 2006). In 1987, the United Church of Christ Commission on Racial Justice released a study titled *Toxic Waste and Race in the United States*. This study, as well as Bullard's research, definitively outlined how black and other minority communities were singled out for hazardous waste sites and how they used the environmental justice frame to organize collectively.

Environmental racism is racial discrimination in environmental policymaking, the enforcement of regulations and laws, the deliberate targeting of communities of color for toxic waste facilities, the official sanctioning of the life-threatening presence of poisons and pollutants in our communities, and the history of excluding people of color from leadership of the ecology movements (Brulle and Pellow 2006).

Bullard traced the environmental justice movement in the communities he studied all the way back to the civil rights movement. The civil rights movement provided a master frame that validates the struggle for rights by other disenfranchised groups (Bullard 1990; Čapek 1993). Churches in the communities Bullard studied were a major catalyst in organizing community members. Just as in the civil rights movement, many important figures of the movement were community leaders who stood up for their rights despite not having the resources to advance their cause (Bullard 1990). In these ways, the civil rights movement shaped the environmental justice movement in the black community. Environmental justice can be distinguished from environmental inequality, which refers to a situation in which a specific social group is disproportionately affected by environmental hazards.

Class has been said to play a role in siting of toxics as well. Studies have demonstrated that the poor and minorities face a disproportionate burden of exposure to environmental health hazards and toxics (Brulle and Pellow 2006). Evans and Kantrowitz (2002) found that there is a relationship between ethic and class characteristics of a community and levels of exposure. Other studies found that in some areas of the country, specifically Southern California, race was not only a strong predictor of siting facilities, but it also explained cancer risk distributions even when controlling for other demographics (Brulle and Pellow 2006). The social dynamics that create and allow environmental inequality to function are the economy and institutionalized racism.

As industrialization expanded and became modernized, the dangers and consequences were

unforeseen. Corporations were concerned only with profits. Polluters argued for siting in locally unwanted land uses (LULUs) because they have less political power and ability to resist. As the environmental justice movement grew throughout the 1980s, many groups organized around minority and poor communities, as these were the places more heavily burdened with toxic waste and pollution (Brulle and Pellow 2006). These community organizations built a framework for social justice that included the following: the right of all individuals to be protected from environmental degradation, public health model of prevention as the primary strategy to prevent harms, shifting burden of proof to the offending entity, allowed disparate impact and statistical weight, and redresses risk through targeted action (Brulle and Pellow 2006).

Even today, lead poisoning continues to be the number one environmental health threat to children in America, disproportionately affecting poor and minority children (Bullard et al. 2008). Black children are five times more likely to suffer lead poisoning, and one in seven black children living in older inner-city housing has elevated lead levels (Bullard et al. 2008). Minorities not only suffer worse consequences from pollution and toxics, but they receive disparate treatment at the hands of the government when attempting to fight against pollution and toxic waste.

Native Americans are also at high risk from toxic threats and the siting of waste facilities near residences (Brook 1998). Native Americans live at the lowest socioeconomic level in the United States. Their lands have been targeted by the government for hazardous waste sitings. One study found that of the 110 commercial nuclear power plants, the government has solicited every tribe, offering millions of dollars for them to host a waste facility (Angel 1991; Brook 1998). This "toxic trade" is appealing to impoverished communities. The categories of people who illegally dump waste on the native land have been referred to as midnight dumpers and native entrepreneurs (Brook 1998). Midnight dumpers are outsiders who do so secretly and illegally. Native entrepreneurs are members of the tribe who stand to gain profit. Ultimately, as Szasz (1994) wrote, "the intersection of race discrimination and exposure to toxic hazards is one of the core themes of the anti-toxics movement" (151).

Toxic Waste Concerns

Concern over toxic waste frequently begins with local citizens who come to draw a causal link between seeping dump sites and a perceived increase in the neighborhood incidence of health problems (Hannigan 2006). Toxic waste sites affect millions of Americans, and two million people live within a mile of a Superfund site, some of the most toxic areas (Laurian 2004). Issues with toxic sites also create environmental and public health risks, stigmatize communities, and affect land use (Laurian 2004). By 2016, approximately 53 million people lived within 3 miles of a Superfund site which is equal to 16% of the US population (EPA 2017). The current data on the EPA website lists 1342 National Priority List Superfund sites. Hazardous waste that is not properly managed could cause adverse health effects on the population within the vicinity (Fazzo et al. 2017).

Krieg (1998) argued that the siting of toxic waste facilities was based on community tax structure and socioeconomic standing of the community in question. Tax structures may affect how dependent a community is on maintaining resources and businesses in the area for investment. As has been argued in other areas of the nation, the need for economic development is a great consideration here. Working-class communities are more affordable land and more favorable political climates for industrialization. In this, Krieg argues that the toxic waste crisis is becoming suburbanized. In his analysis of 44 towns, working-class neighborhoods faced greater siting risks than middle-class towns. One conclusion to be drawn is that environmental movement activity creates conditions unfavorable to capital accumulation and pushes toxic waste producing industries into other areas (Krieg 1998).

Although it is possible for chemicals to migrate off-site from landfills, there is not much known on the extent to which citizens living near landfill

sites are exposed to chemicals (Vrijheid 2000). For example, there were studies done that followed the contamination of two drinking-water wells in Santa Clara County, California, with chlorinated solvents that had leaked from an underground waste storage tank. Near one of these sites, there were reports of a cluster of adverse pregnancy outcomes (Vrijheid 2000). As is true for many public health issues tied to environmental hazards and toxic waste, effects of the exposure for the population are difficult to establish. Several studies suggest a relationship between proximity to landfill sites and adverse pregnancy outcomes. Single-site studies focusing on one landfill and community demonstrate an increase in infants with low birth weight, which is considered to be a marker of the effects of chemical exposure. Multi-site studies are too few to determine further health consequences, though birth defects have been reported, but it is difficult to establish causality. This is especially true for cancers, as evidence for a causal relationship between landfill exposure and cancer is weak, and there are long latency periods (Vrijheid 2000). Proof of causation in the case of cancer and suspected environmental hazard-related diseases is very difficult. This proved to be the case in Louisiana's chemical corridor as well, as epidemiology studies have failed to prove or disprove what many residents strongly believe, that their constant exposure to toxic waste and hazardous materials causes cancer and death (Allen 2003).

Other research examines the proposition that since the growing public concern and opposition to waste facilities, siting follows the path of least political resistance, resulting in environmental inequality. Saha and Mohai (2005) performed a longitudinal analysis on Michigan over 30 years and found patterns of disparate siting for facilities after 1970. Because Love Canal put toxic waste exposure on the radar of many Americans, it also heightened fears that other neighborhoods were unknowingly at risk and added fuel to the NIMBY phenomenon (Saha and Mohai 2005). The antitoxic movement took hold in many middle- and working-class neighborhoods, and citizen involvement increased as a result.

Flint and the Water Crisis

In 2014, Flint, Michigan, began to experience an ongoing water crisis. The drinking water source for the city was switched from Lake Huron to the Flint River, a more cost-effective water supplier. This was done in anticipation of a $25 million deficit, while the city constructed a new pipeline (Reilly 2017). The water was insufficiently treated, and the city announced the presence of bacteria as lead had leached into the drinking water. A state of emergency was declared in 2016, and residents were informed to use bottled or filtered water only. Residents experienced a series of health effects from lead contamination. Government officials initially denied that there were problems and refused to go back to the original supplier, even though it was common knowledge that Flint River was greatly polluted (Reilly 2017). Doctors conducting research found that the percentage of children in Flint with lead poisoning had doubled in 2015 (Gupta et al. 2016).

The incident is reminiscent of the Hinkley, California hazardous waste event, when Pacific Gas and Electric Company dumped millions of gallons of chromium-tainted wastewater into unlined water reservoirs during the 1950s and 1960s. It was absorbed into the groundwater, and after extended litigation in the 1990s, the issues with wastewater and pollution continue even today.

There is an ongoing environmental toxic contamination in today's world (Miller and Wesley 2016). Through congressional testimony on the incident, the public heard about deals that resulted in the poisoning of households. To that end, some have argued that the Flint water crisis is a form of violent assault against residents (Miller and Wesley 2016). The fear of ongoing health consequences that may lie dormant is a constant source of anxiety for victims of toxic exposure. Social trust is damaged beyond repair, and citizens lose any faith in government officials. Any sense of safety at home is lost and changed. Lead contamination is a serious health issue. As Miller and Wesley (2016) write, "in light of biopolitical considerations of lead poisoning risks, it is important to consider

who bears the risks for decisions made without social consent of those governed, to identify how risks and uncertainty, with their associated costs, are distributed throughout communities, and address the restorative responsibility link between the public and private spheres" (74).

Conclusion

Disasters that result in toxic contamination disrupt the social fabric of the communities where they happen (Miller and Wesley 2016). As industrialization and technological advancements increase in society, we are left at risk to toxic waste and hazards. While various social movements have garnered attention for environmental hazards and toxic waste in households, the water crisis in Flint, Michigan, demonstrates this is an ongoing battle, where minority and poor communities still suffer a disproportionate impact and corporations are not held liable for their pollution and improper waste disposal, continuing to put communities at risk.

Industrial Control System

Marie-Helen Maras
Department of Security, Fire, and Emergency Management, John Jay College of Criminal Justice, City University of New York, New York, NY, USA

Keywords
Industrial control system · Critical infrastructure

Definition

An industrial control system is a general term used to describe systems that are designed to monitor, oversee, manage, and/or support processes of critical infrastructure.

Introduction

An industrial control system is a general term used to describe systems that are designed to monitor, oversee, manage, and/or support processes of critical infrastructure (i.e., "the physical and cyber systems and assets that are so vital to the United States that their incapacity or destruction would have a debilitating impact on our physical or economic security or public health or safety"; DHS n.d.). The United States has 16 designated critical infrastructure sectors (CISA n.d.): chemical; commercial; communications; critical manufacturing; dams; defense industrial base; emergency services; energy; financial services; food and agriculture; government facilities; healthcare and public health; information technology; nuclear reactors, materials, and waste; transportation systems; and water and wastewater. These critical infrastructures are both publicly and privately owned. The vast majority of critical infrastructure sectors, however, are privately owned (FEMA 2011). This private ownership complicates efforts to harmonize measures designed to protect and secure the ICS of these sectors from cybersecurity threats and vulnerabilities.

Cybersecurity Threats and Vulnerabilities

Industrial control systems are vulnerable to internal cybersecurity threats and external cybersecurity threats that could compromise or exploit the confidentiality (i.e., prevention of unauthorized access), integrity (i.e., preservation of the accuracy and trustworthiness of data), and availability (i.e., accessibility) of systems, networks, services, and data (Maras 2016; UNODC 2019). Internal threats, like insider threats, are those posed and committed, in whole or in part, by individuals within an organization or agency, who have authority, access, and/or privileges

https://doi.org/10.1007/978-3-319-70488-3

within an organization/agency to, for example, steal data or engage in sabotage (e.g., modifying data or damaging systems). ICS are also vulnerable to external threats, predominately because they were not originally built with cybersecurity mind.

ICS were previously made up of isolated systems and separate networks. The original systems were primarily secure systems protected against cybersecurity threats – at least remote unauthorized access to these systems. Today, however, this has changed. ICS are now networked to increase efficiency of operations and facilitate the sharing of real-time information about their operations. This networking enables the remote access of ICS and exposes these systems to cybersecurity risks. ICS are, thus, vulnerable to external cybersecurity threats because of their design and operations.

Certain ICS are still legacy systems – proprietary systems that do not contain standard architecture and syntax (DHS 2016; Stouffer et al. 2015). This is both a negative and a positive feature of ICS. It is a negative feature because proprietary systems are often hard to manage and operate as they require specialized knowledge. It is a positive feature because perpetrators, who learn the inner workings of these systems and gain access to them, cannot use this knowledge to gain access to other industrial control systems. Other ICS are off-the-shelf or standardized (DHS 2016; Stouffer et al. 2015). Off-the-shelf ICS are used because they cost less than proprietary and legacy systems and are easy to use, making them more effective and efficient to manage and operate. Nevertheless, off-the-shelf ICS afford perpetrators with the opportunity to learn about the inner workings of these systems and to gain unauthorized access to them. These perpetrators can then use this knowledge or share this knowledge with others, to gain unauthorized access to other off-the-shelf ICS used in similar or different critical infrastructure sectors. Because these systems could be located in different parts of the world with varying degrees of security, perpetrators can access these systems from countries and/or facilities that are not well protected and can use the knowledge gained from this unauthorized access to target other countries.

Securing ICS

Practical strategies for achieving security of industrial control systems include risk management; physical security measures (e.g., access controls and security guards); personnel security measures (e.g., background investigations and robust recruitment, hiring, selection, and retention policies); network and security architecture (e.g., network segmentation and "specific controls and their strategic placement within the network or systems to establish layers of security"); host security (e.g., ICS update and patch management and strong authentication measures); and security monitoring (e.g., audit logs that provide information about user activity, such as files access, modification, download, and/or removal, and other activities, intrusion detection systems, and intrusion protection systems) (DHS 2016, pp. 4–34). Vendor management and vendor security are also integral facets of securing ICS (DHS 2016). Here, vendors, their products, and services should be properly vetted and monitored to not only ensure the quality of goods and services but also to verify that cybersecurity policies, procedures, and practices are followed by vendors. Supply chain compromises in the form of software or hardware with malware and vulnerabilities in software applications have brought home the lesson that attention needs to be paid to this area. Finally, clear ICS security policies and procedures, as well as policies and procedures on the misuse of ICS, are also needed and should be communicated to all ICS employees (DHS 2016). ICS owners, users, and, to the extent that it relates to them, vendors, should also receive training on these policies and procedures (DHS 2016).

Conclusion

Industrial control systems are vulnerable to cybersecurity threats. To protect ICS, measures are needed to detect cybersecurity threats, restrict unauthorized access to ICS, and protect ICS from misuse and criminal exploitation. The type of security measures chosen, however, depends on the type of ICS.

Influence of Risk Perception on Event Risk Management and Decision-Making

Peter Ashwin
Event Risk Management Solutions, Boise, ID, USA

Keywords

Risk Management · Event Management · Risk Perception · Risk-based Decision-making

Introduction

In today's global risk society, event organizers find themselves in an environment characterized by diverse and dynamic risks ranging from home-grown violent extremism, cyber-threats, event cancellations due to severe weather, and a saturated market which offers locals and visitors a diversity of competing events to choose from Berlonghi (1990), Tarlow (2002), Rutherford Silvers (2008), and Piekarz et al. (2015). Due to the serious impacts from these issues and incidents, risk management should be viewed by event organizers as a fundamental responsibility for planning and delivering safe and secure events (Rutherford Silvers 2008). Furthermore, a rational and structured approach to risk management will enhance the event organizers' ability to make appropriate decisions within fast-paced, complex,

and uncertain environments (Hillson 2016). However, risk management is also prone to subjectivity, bias, and error leading to exaggeration and overestimation or underestimation of risk which may result in ill-informed decisions (Lupton 2013).

It is sometimes said that risk management is too subjective. To what extent is this true and what are the implications for event organizers? This entry will critically analyze whether risk management within the events industry is too subjective and if subjectivity positively or negatively influences the effectiveness of decision-making.

First, the interconnected concepts of risk management, uncertainty, and subjectivity must be defined to form the basis to explore whether risk management is rational and objective or, conversely, subjective. Second, the theoretical perspectives underpinning risk perception will be analyzed to explore how these sociocultural perspectives may influence whether a rational or subjective approach to risk management is more effective for event organizers. Third, a critical analysis of whether the effectiveness and credibility of risk-based decisions by event organizers is positively or negatively influenced by their perception of risk and their organizational culture. Fourth, the notion of risk-based decision-making by event organizers will be examined to identify how event organizers identify with and respond to risk within today's global risk society (Beck 2006).

Finally, it will be noted that despite the gaps in evidence and literature on event risk management (Khir 2014; Robson 2009), this entry will argue that the risk management approach adopted by event organizers is primarily subjective; however, this approach does not negatively impact their decision-making ability under ambiguous conditions. Moreover, it will be argued that if event organizers adapted their subjective approach with a rational approach to risk management, this combined risk-based decision-making process would enhance their organizational capability to prepare for, respond to, and recover from adverse risk events (Talbot and Jakeman 2009).

Managing Risk in Today's Uncertain World

Today's global risk society is volatile, uncertain, complex, and ambiguous (Beck 2006; McCaughey et al. 2017). National boundaries are blurred, and interconnected markets are exposed to delocalized risks with consequences that may stretch over extended or indefinite periods of time (Beck 1992, 2006). This section of the entry will explore the concepts of risk and event management to examine how risk management is considered by event organizers.

First, while there is no definitive or widely accepted definition of what an "event" is, an event can be best described as "an opportunity for leisure, social or cultural experience outside the normal range of choices or beyond everyday experience" (Getz 1997, p. 4). Furthermore, the events industry encompasses a diverse range of activities that includes festivals, parades, meetings, conventions, expositions, sport, and other special events. Within the industry, event organizers are responsible for the research, design, planning, coordination, and execution of events (Goldblatt 2011).

In order to understand how risk is managed, one must first explore the concept of risk. ISO 31000 (2018) describes risk as the consequence of an organization setting (ecosystem) and the pursuit of the achievement of their mission and objectives against an uncertain environment influenced by internal and external factors which the organization may not completely control (Purdy 2010, p. 882). While risk generally refers to undesirable events, risk also provides opportunities for an organization to achieve favorable outcomes in pursuit of their mission and objectives (Hopkin 2010). Moreover, when risks are effectively managed, the chances of achieving stated goals and objectives will be optimized (Hillson 2016).

Berlonghi (1990) was among the first academics to identify risk management as an integral part of the event management process: the process by which an event is planned, prepared, and produced (Goldblatt 2011; Rutherford Silvers 2008). Within the events context, risk management can

be described as the process of making and carrying out decisions that minimize the adverse effects of the potential losses of an event or simply stated as "making events as safe and secure as possible" (Berlonghi 1990, p. 3), or alternatively

> a comprehensive approach to risk management that engages organizational systems and processes together to improve the quality of decision making for managing risks that may hinder an organization from achieving its objectives. (US Department of Homeland Security 2011, p. 13)

While there is a relatively large body of literature asserting that risk management is fundamental to planning and delivery of safe and secure events, there remains a gap in research and literature specific to event risk management (Khir 2014; Robson 2009). Furthermore, it is also noted that the existing body of literature on risk management within the events industry focuses in most part on insurance and legal obligations, typically agreements, indemnifications, and waivers (Rutherford Silvers 2008).

Effective risk management requires the assessment of inherently uncertain events through two dimensions: (1) how likely is the risk event and (2) what is the impact to the organization's objectives? The probabilistic risk assessment (PRA) is one of the most commonly used tools to quantify risk through an assessment of the aforementioned factors of likelihood (probability) and consequence (Ostrom and Wilhelmsen 2012).

Talbot (2011) argues that if sufficient rigor has been put into defining the context of the risk statement, the likelihood, and the consequence metrics, then a meaningful risk estimate (risk rating) can be quickly and consistently obtained from a risk matrix. Although semiquantitative in nature, risk matrices provide a focus for decision makers to identify and manage the highest priority risks and provide a simple visual presentation of these ranked risks (Hopkin 2010).

Additionally, Talbot (2011) contends that the inherent limitations of risk-based decision-making within uncertain environments and the fundamental processes of human risk perception mean that the subjective decision-making will always be part of the risk assessment process. Following on from Talbot's argument, the next section of the essay explores the theoretical perspectives underpinning risk perception and how these sociocultural perspectives may influence the way event organizers identify and manage risk.

The Influences of Risk Perception and Heuristics

It can be said that event organizers' risk perception is not only based on perceptive or objective fact, but also by the individual's background, experience, and the organizational culture (Robson 2009). In following section of the essay, techno-scientific and sociocultural perspectives underpinning risk perception will be examined to explore how these perspectives influence an event organizers approach to risk management.

There are arguments on both sides over whether risk is subjective or objective or a combination of both, noting that there is an inevitable element of "subjectiveness" within human judgment and decision-making (Bradbury 1989, cited in Lupton 2013, p. 28). Subjectivity can be defined as the influence of personal beliefs or feelings, rather than facts (Cambridge English Dictionary 2016).

The phenomena of risk perception have been theorized in social scientific literature through three major perspectives: (1) the naïve realist or techno-scientific, (2) cognitive psychology, and (3) sociocultural (Lupton 2013, p. 26). The techno-scientific perspective contends that risk is a product of a hazard (or risk source) with calculations of likelihood and the consequences of a risk event (Lupton 2013, p. 27). The underlying premise is that risk can be measured and calculated which is also consistent with the approach outlined within ISO 31000 approach. One weakness of the techno-scientific theory is that the "lay person's perceived lack of risk knowledge and how their response to risk is based on inferior and unsophisticated sources of knowledge such as intuition" (Lupton 2013, p. 28). Counter to this argument, Wynne (1989, cited in Lupton 2013, p. 148) argues that lay persons' assessment of risk

incorporates their preestablished knowledge of how relevant industries and regulatory bodies have tended to deal with risk in the past. This position is supported by the social-constructionist argument that risk judgments are in part based on prior knowledge, personal embodied experiences, discussions with others, and access to expert knowledge (Lupton 2013, p. 45).

Like other lay persons, event organizers often rely on intuitive risk judgments (risk perception) to explain responses to risk. Rogers (1997) argues that risk perception rests on a foundation of overall experience which seldom incudes direct experience with the risk event. Within the events environment, risk perception has been described by Berlonghi (1990, p. 19) as being "the concerns of the various entities involved in the event" and that the risks identified by the event organizers may not be accurate nor verifiable, particularly if in the absence of an event risk assessment. Given their shortfall in experience with risk events, event organizers often rely on industry associations like the International Festival and Events Association (IFEA) to gain

> a shared, accumulated experience to determine which foreseeable losses are most probable, losses which are the most harmful and which harms (risks) may be preventable to assess and manage risk based on their previous risk event experience or that of other event organizers. (Douglas 1985, cited in Lupton 2013, p. 54)

One heuristic process that has special relevance for risk perception is known as "availability" bias (Tversky and Kahneman 1973 cited in Slovic 2000, p. 105). Event organizers intuitively use this process to judge an event as likely or frequently occurring, if the circumstances are easier to recall or have been experienced. Frequently occurring events are generally easier to recall than a rare event. In the absence of documented risk management plans (Robson 2009; Blerter and ERMS 2019), it is inferred that the majority of event organizers rely on intuitive risk judgments to manage their organizational and event risks. There is also an argument that an individual's risk perception could be changed, should additional information be available (Rogers 1997).

Event Organizers Approach to Risk Management

Event organizers seldom have statistical evidence or supporting event data (Robson 2009) to make informed judgments on the likelihood and consequences of risk. This is due to event organizers' lack of event documentation (after-action reports, near miss, and incident reports) which provide risk insights and proactive information on the effectiveness of the risk control environment (Reason 1997). In the most part, event organizers rely on their collective organizational memory to make inferences and decisions based on what they remember observing or experiencing during previous risk events; this heuristic process is referred to as judgmental bias (Slovic 2000). Based on this inference, it can be argued that event organizers use heuristics to make risk-based decisions in fast paced, uncertain environments. This opinion is supported by Slovic (2000, p. 41) who argues that people may judge risk and the benefits of hazards more efficiently under time pressure using heuristics rather than analytical processing and that human judgment is needed to interpret risk information and findings to determine the risk estimate.

Event organizers proactively seek out information on risk to support their risk judgment for identifying and selecting an appropriate course of action to avoid or mitigate the identified risk phenomena for their event or organization (Robson 2009). Furthermore, as a lay person, an event organizer's subjective response to risk should not be considered erroneous or biased if their opinions differ from that of expert risk assessments (Lupton 2013). The effectiveness and credibility of this subjective risk management approach will be further examined in the next section.

It is argued that scientific reasoning and experience are not mutually exclusive and that both should contribute to a rational assessment process that informs judgment that considers the totality of risk in a global risk society (Young 1995, cited in Lupton 2013). In this section, the level of subjectivity within the event organizers risk management approach will be further examined to determine whether it positively or negatively

influences their perception of risk or their approach to risk management.

There is an important contrast between the literature describing other for-profit business perception of risk as compared to the event organizers. For-profit businesses will willingly take risks in order to pursue opportunities to increase market share. In comparison, not-for-profit event organizers, the concepts of dread and the fear of the unknown have a profound influence on their perception of risk (Slovic 2000). Event organizers perceive risk as being negative and seek to avoid or reduce identified risks to a level as low as possible (Robson 2009). Furthermore, there is a common misperception amongst event organizers that insurance and legal documentation constitutes a risk management plan as compared to a structured approach like ISO 31000 which recommends documenting risk information within a risk register including the risk classification system, risk statements, risk owners, assessed risk levels etc. (ISO 2018; Piekarz et al. 2015).

While some techno-scientific theorists argue that a subjective approach to risk management is perceived as ineffective from a techno-scientific perspective, Beck (1999, cited in Lupton 2013, p. 80) argues that one should not have to choose between a natural-scientific objectivism (naïve realist) or a cultural relativism (subjective) approach for risk management, but rather use each when it is appropriate to understand the complex and ambivalent nature of the risk environment.

An example of this approach is Hancock's (2019) "forced risk ranking" approach which offers a simplified alternative to a PRA approach for ranking and prioritizing risks. Event organizers (including their operational line managers) are asked to identify their top ten risks within their organizational risk ecosystem, and then assign a numerical ranking value from one to ten to produce an aggregated score to rank and prioritize their risks. Hancock contends that the results from a forced risk ranking have shown much more separation among the risks, particularly when comparing results between different management groups (executives and managers). The other benefit of this approach is that there is no requirement to construct probability and consequence assessment scales to rank and prioritize risk. This simplified approach offers event organizers an opportunity to add process to their subjective risk assessments to better inform future decision-making and communication of risk information within the organization.

Decision-Making within the Events Environment

Talbot (2011) argues that subjective decision-making will always be part of the risk management process no matter what tool is used, and that these processes still effectively support risk informed decisions. In summary, there is insufficient evidence to suggest that a subjective risk management approach by event organizers is ineffective or lacks credibility. Following on, the next section will further explore decision-making processes by event organizers. Anecdotal evidence from a recent events industry survey conducted by Blerter and ERMS (2019) targeting CEOs and executive directors indicated only 17% of the 163 respondents were confident that their event team was mission ready, that is to say, operationally ready, organizationally resilient, and confident in their ability to respond to and make decisions under adverse and uncertain conditions. Event organizers, like other professionals, have great difficulty making decisions and judgments under uncertainty (Plous 1993). In this section, the concept of risk-based decision-making will be examined to identify how event organizers make decisions within uncertain and complex operating environments. As previously highlighted, there is little supporting evidence and literature on how event organizers (including senior leaders and operational managers) make risk-based decisions in situations that may involve consequences across multiple levels from individual to organizational to societal.

Rational theories of decision-making rest on the assumption that decision-makers follow a rational procedure for making decisions, selecting the option that will produce the best outcome (Laybourn 2003). While this rationale may be applicable in the military as part of the military

appreciation process in the selection of courses of action, this is not necessarily a common approach within the events industry. Are event management decisions driven by a deliberate and rational analysis or a more intuitive, heuristic-based approach to decision-making?

Given the current gaps in literature and scant research on event risk management and risk-based decision-making approaches by event organizers, literature on decision-making related to emergency first responders was reviewed for comparative analysis. The selection of this comparative analysis approach was based on the reasoning that both event organizers and first responders often operate within similar environments characterized by the requirement to make time critical decisions under uncertain conditions, constrained by availability of information.

Klein's (2008) recent research on recognition of prime decision model demonstrates that decision-making is a perpetual process, situationally based to facilitate fast effective decision-making, based on previous experience and intuitive knowledge that enables the decision-maker to generate fast and effective courses of action. The recognition primed decision model evidences that fast, effective decision-making is possible within time critical situations when the decision-maker has the expertise and situational awareness, combined with a battery of experience based, intuitive knowledge (Klein 2008). Similarly, research into naturalistic decision-making focused on how first responders utilized their expertise and experience to make effective decisions through utilizing systems of work known to have been successful in previous situations, often under uncertain and high stress situations (Ash and Smallman 2010). Event organizers like first responders will rarely have the necessary information and resources for an analytical based decision-making process (Tarlow 2002, p. 37), whereas the concept of "satisficing" is evidenced to more efficient under these conditions (Klein 2008).

It can be argued that the inherent limitations of event organizer's risk perception shape their decision-making under uncertain conditions, particularly given the influence of external "dread risks" over which the event organizer has no control. Event organizers risk perceptions of dread risks have become even more evident as a result of recent active shooter incidents which occurred at the 2018 Harvest 91 county music festival (Las Vegas) and the 2019 Garlic Gilroy Festival (California). Furthermore, evidence has shown that the individual event organizer's risk perception will always influence the subjectivity of the risk assessment process (Talbot 2011; Laybourn 2003). Additionally, research and literature on naturalistic decision-making provide a body of evidence that this decision-making approach is adaptable and viable for event organizers. Naturalistic decision-making allows event organizers to leverage their expertise, experience, and intuition to reach timely and effective satisficing decisions in fast-paced event environments.

Conclusion

In conclusion, controversy still remains whether risk management is too subjective. While it is acknowledged that event organizers approach to risk management is fundamentally subjective, it can be argued that these subjective risk assessments are equally rational as a scientific expert assessment (Lupton 2013). Event organizers construct their risk judgments based on insights from embodied risk experiences, organizational memory, and access to a collective industry body of risk knowledge shared through industry associations and other expert resources. While risk-related choices and decisions by event organizers are often driven by their subjective approach to risk management, this by no means indicates that this approach to risk management is ineffective or less credible. Nor is there any evidence to the contrary.

In light of the recent "dread" risk events that have recently occurred within the events environment, there is an increasing awareness among event organizers that a more structured approach to risk management is required to protect the value and reputation of their events and organization while pursuing their mission within an operating environment characterized by complexity and uncertainty (Rutherford Silvers 2008; Blerter and ERMS 2019). Similar to other organizations, there is also an increasing requirement for event

organizers to demonstrate an evidence-based approach to risk management with the ability to explain the rationale behind those decisions in clear, objective, and transparent terms (DHS 2011). However, in contrast, while most event organizers talk about risk, the majority of event organizers concede that they do not have a documented risk management plan for their event (Sturken 2005, cited in Robson 2009; Blerter and ERMS 2019).

In closing, while the evidence presented in this essay concludes that event organizer's risk management approaches are more subjective than rational and can be regarded as effective; event organizers must continue to seek opportunities to strengthen their current subjective risk management practices through a more objective approach based on international and industry risk management guidelines like ISO 31000. The future of events and their resilience to uncertainty will continue to be influenced by the ability of event organizers to make effective risk-based decisions under uncertain conditions within today's global risk society.

Definition

Insider threat refers to one or more individuals with authorized access to critical facilities, materials, or information who could attempt unauthorized removal or sabotage or who could aid in an external adversary to do so.

SAND2019-0545 J. Sandia National Laboratories is a multimission laboratory managed and operated by National Technology and Engineering Solutions of Sandia, LLC., a wholly owned subsidiary of Honeywell International, Inc., for the US Department of Energy's National Nuclear Security Administration under contract DE-NA-0003525.

Introduction

While physical security is often perceived as guards, gates, and guns, all infrastructure security events have a human dimension. Any individual with authorized access to or knowledge of a site has the potential to play a role – positive or negative – in a security event. In most cases, this human dimension manifests in how personnel play a positive role in preventing, detecting, and responding to security events. In other cases, however, personnel play a negative role and facilitate security events through a lack of awareness, negligence, or unintentional acts. In extreme cases, individuals cause security events by committing *intentional* and *malicious* acts against critical facilities, materials, or information. These individuals could be *anyone*, to include those with regular (e.g., staff, management, janitorial, or security personnel), irregular (e.g., contractors, inspectors, or first responders), and limited (e.g., visitors or former employees) authorized access. This constitutes the so-called *insider threat*, a term defined by the National Insider Threat Task Force (2016) as:

> the risk [that] an insider will use their authorized access, wittingly or unwittingly, to do harm to their organization. This can include theft of proprietary information and technology; damage to company facilities, systems or equipment; actual or threatened harm to employees; or other actions that would prevent the company from carrying out its normal business practices. (p. 3)

Thus, unlike external threats, the insider threat is difficult for organizations to address and mitigate because malicious insiders have "legitimate authorized access to your most confidential, valuable information systems, and they can use that legitimate access to perform criminal [or malicious] activity" (Cappelli et al. 2012, p. xviii). Although "many institutions have 'perimeter defenses' (gates, guards, access controls, and computer firewalls) [they] are nonetheless vulnerable to insider theft or destruction of critical data [materials, or facilities]" (NITTF 2016, p. 2). Most individuals will never attempt a malicious insider attack, but because any person with authorized access has the *potential* to do so, there is a need to adequately

address and mitigate the insider threat. This chapter will begin with a description of insider advantages, attributes, and motivations, as well as categories by which to evaluate potential insider threats. It will then outline broad concepts and strategies for preventing and mitigating insider threat attempts – to include steps to be taken *before* and *after* personnel are granted access, authority, and knowledge to critical pieces of infrastructure.

Insider Threat Advantages, Attributes, Motivations, and Categories

Unlike traditional, external threats that rely on overwhelming shows of force, the insider threat uses stealth (blending in to normal operations) or deceit (e.g., spoofing normal operations) to perpetrate a malicious act – leveraging key advantages of legitimate, authorized access to critical facilities, materials, or information. Authorized access to sensitive facilities or materials provides insiders with *time* to collect additional information or develop a plan for an attack. Potential insiders can use this time to operate at the margins of normal business practices (e.g., steal small quantities of materials below reporting thresholds), establish new behavioral patterns (e.g., regularly access a new vault), or change operational procedures (e.g., grant themselves network administration permissions) to avoid suspicion and detection. Additionally, insiders who wish to carry out a malicious attack have the *tools* necessary to do so – they know what capabilities the facility has (such as a crane to lift heavy items) and consequently do not have to bring in their own tools. For external attacks, a traditional concern for security designers is how many tools an adversary can bring into a facility. In contrast, an insider already has knowledge of and access to the necessary tools.

Time and access to tools lend insiders a third distinct advantage – the ability to *test* the system to identify whether an attack might be detected. Finally, insiders have the potential to leverage their position within the organization to influence the behavior of others. The influence of insiders can lead others to wittingly or unwittingly aid the insider with the attack (e.g., *teamwork*). Not all individuals who help insiders do so knowingly, as insiders can use their position to convince others to help in seemingly routine or benign ways. However, multiple insiders knowingly working together can be especially disastrous. The four advantages discussed above – time, tools, tests, and teamwork – increase the importance of addressing and mitigating the insider threat. Further, one way to describe insiders is in terms of four key attributes: access, authority, knowledge, and motivation.

Access includes the permission to be in a facility (or certain locations within a facility), to use specific materials or technology, and to view or obtain sensitive information. Typically, control over access is implemented to protect sensitive facilities, materials, and information. However, the primary distinguishing attribute of insiders is their permission to be in close proximity to or influence the use of sensitive facilities, materials, and information without setting off alarms or causing concern. Individuals with this level of access include all operational employees (such as staff and all levels of management) and support employees (such as the janitorial staff, security personnel, and other staff considered ancillary to a facility's primary objective). In addition, individuals with irregular access (such as inspectors, regulators, visitors, first responders, and maintenance personnel) can also pose a potential insider threat, as they have access to sensitive facilities, materials, or information that can be exploited in an insider attack. Consider, for example, "evidence of potential tampering as the cause of the abnormal condition" after engine coolant was found in the oil system of a diesel generator at the San Onofre Nuclear Power Plant in 2012 (Bunn and Sagan 2014, p. 1, footnote 2). This describes a potential insider scenario because not many individuals have permission to be near diesel generators at nuclear power plants, let alone to access the oil system without raising suspicion.

In addition to access, some insiders have *authority* or the power to influence behaviors or outcomes of people, procedures, or operations. Authority can be formal, to include hierarchical power structures (e.g., management and leadership

within an organization), control over communications protocols (e.g., supervising the central alarm station), and direct responsibility over sensitive operations. In addition, authority can be informal, to include influence driven by professional seniority or expertise, cultural norms, familial lineage, tribal affiliation, or personal affection. In addition to influencing people, authority can also influence operations – for example, an individual with authority could potentially delay the assessment and communication of an alarm to security personnel or ignore (and fail to report) patterns of unauthorized access of critical computer servers. Authority can even impact procedures, such as changing the protocols for retrieving items from a high security vault or making it more difficult to report anomalous security behaviors. Here, the £26.5 million heist from the Northern Bank case in Northern Ireland – in which one of the bank managers was convicted of an active role – is illustrative (Bunn and Sagan 2014).

Knowledge is an insider attribute that indicates a more detailed understanding of critical facilities, materials, or information than is held by the general public – and affords a potential insider additional benefits for carrying out an attack. First, insiders have knowledge of detailed facility layouts, operations, and normal business practices, while an outside attacker would know much less about a facility. Insider knowledge may include how to avoid or defeat protections at a facility such as security force capabilities and locations (or deployment strategies), details of security systems, or bypass activities for implemented protections. In addition, insider knowledge can include how to optimize targeting during an attack (e.g., to maximize damage to the facility or steal the most critical assets). Finally, insiders can combine all their knowledge to carry out an insider attack more expeditiously. Illustrating the role of knowledge in insider threat cases, one database demonstrated that "guards were responsible for 41 percent of insider thefts at non-nuclear guarded facilities" (Bunn and Sagan 2014, p. 4). For additional details, descriptions, examples, and case studies please see Hoffman et al. (1990) and Sagan and Bunn (2017) in the recommended readings list.

These attributes – authority, access, and knowledge – alone do not transform an average employee into an insider. Most often, this transformation is triggered by a *motivation* – or the reason(s) driving a set of actions or behaviors. There is no single motivation guaranteed to transition an individual with authority, access, and knowledge into a malicious insider, as different external or internal drivers motivate different individuals to act against sensitive facilities, materials, or information. For example, consider an individual with environmentalist sympathies who gains employment at an oil refinery in order to access and damage operational control rooms. This individual exhibits a *political* motivation, where the malicious act was used to raise awareness for a government or policy issue. Other common motivations include:

- *Ideological*: acting in response to a system of ideas and ideals, especially political beliefs.
- *Financial:* wanting or needing additional money.
- *Personal/disgruntlement:* an individual response to a perceived slight.
- *Psychotic*: mental instability driving behaviors.
- *Coercion*: external pressure applied to an individual, their family, or their assets to influence behavior (Homoliak et al. 2018; Tsenov et al. 2018).

Each distinct motivation may lead to insight for both the level of potential malicious intent and the likelihood the attempt will occur – and, therefore, helps identify appropriate mitigation strategies. For example, a disgruntled employee with a personal motivation is most likely to commit an insider attack in the 60 days before or after they are fired. This means facilities should more diligently monitor physical and cyber security in the days following an employee dismissal (e.g., cross-check access and change logs) (Collins et al. 2016). Ultimately not all insiders will attempt or carry out a malicious attack, but when insider opportunity is combined with insider motivations, an insider attempt becomes more likely.

Access, authority, knowledge, and motivation can be combined to define categories of potential insiders to understand the range of possible

malicious actions. Here, several questions help scope the range of insiders:

- Is the insider internally (e.g., disgruntlement) or externally (e.g., coercion) motivated toward malicious acts?
- What level of actions or involvement is the insider willing to commit in support of the malicious act?
- How violent is the insider willing to be in support of the malicious act?

The answers to these questions describe different roles insiders may take during a malicious act against sensitive facilities, materials, or information. If an insider is non-violent and does not actively participate in the malicious act, they are categorized as a *passive insider*. Passive insiders may intentionally (or unintentionally) pass information to an external adversary or may unintentionally aid in a malicious act (e.g., leaving a computer workstation unlocked) but will often stop if they believe they have been detected. These insiders may be looking to make extra money or could be coerced by an adversary who is blackmailing them in exchange for information. If an insider is non-violent but willing to contribute more actively to a malicious act, they are categorized as a *non-violent, active insider*. Active, non-violent insiders may leave doors unlocked, turn off security cameras, or grant unauthorized access to a computer network. Typically, active, non-violent insiders work with external adversaries (or other insiders) to achieve malicious aims, but they do not conduct the act themselves. If an insider is violent and willing to contribute even more actively to a malicious act, they can be categorized as a *violent, active insider*. Active, violent insiders likely execute the malicious act themselves – either with or without external help. Active, violent insiders are willing to inflict bodily harm on others in the facility and could have multiple motivations for the malicious act. These three categories help explain the insider threat and help identify best practices for detection, prevention, protection, and mitigation.

Many insiders have the access, authority, and knowledge to carry out an attack, giving them an *insider opportunity*. Yet, potential insiders also need a driver (or trigger event) to initiate an insider attack, requiring *insider motivations*. This suggests that an *insider attack* results from the combination of an *insider opportunity* (a function of access, authority, knowledge) and *insider motivations* (a function of internal or external drivers toward a malicious act).

Preventative Measures Against Insider Threats

While it is impossible to eliminate the insider threat, one method for identifying how to appropriately respond is evaluating individuals along a spectrum of access, authority, and knowledge. From this perspective, there are three states in which an insider can exist (Cappelli et al. 2012; Homoliak et al. 2018): (1) those applying for authorized access (e.g., job applicants or visitors); (2) those with authorized access – and presumably knowledge (e.g., employees, contractors, visitors); and (3) trusted individuals with additional opportunities (e.g., increased access permissions, management). People in each of these three categories have varying levels of access, authority, and knowledge which require different responses and technological, procedural, and administrative controls.

Preventative measures are mitigations aimed to prevent insider threat opportunities before they occur. More specifically, the goals of preventative measures are to exclude potential insiders by identifying undesirable behavior or characteristics *before* allowing access and to minimize opportunities for malicious acts by limiting access, authority, and knowledge. Preventative measures can take place before individuals are granted access, such as during the hiring process for employees, or through a set of procedures laid out for irregular access, like visits from first responders. However, preventative measures can also take place after access has been granted – though post-access preventative measures are more difficult to implement. The two most successful and well-known preventative strategies include trustworthiness programs and promoting strong security culture.

Trustworthiness programs have no official or common definition, but a working definition would include all efforts, initiatives, and processes to ensure that employees are vetted and found to be responsible, upstanding, and principled. Key elements of trustworthiness programs include a threat or risk assessment, well-defined personnel security requirements, effective implementation of the program, and regular review and evaluation of effectiveness. Delving further into these key elements, a threat or risk assessment should consider potential adversaries including their intent, capabilities, and tactics, understand potential targets at each facility, and understand possible insider motivations. The risk assessment should be used to scale the trustworthiness program to the risk at a given facility and inform personnel security requirements. The second key element, personnel security requirements, should define information and physical access levels, set eligibility criteria for access, and be codified through legal or regulatory mechanisms. Third, trustworthiness program implementation should establish standardized personnel screening processes that could include pre-employment background checks, psychological or medical evaluations, adjudication mechanisms for handling disputes, and continued reinvestigation. Finally, trustworthiness programs should be regularly reviewed and evaluated and anomalous activities and incidents should be thoroughly investigated and reported. Examples of trustworthiness programs include the Human Reliability Program (US DOE), Access Authorization Programs (US NRC), and Personnel Security Programs (implemented internationally).

Unlike trustworthiness programs, which aim to determine if a person should be allowed access, the goal of security culture is to promote and reinforce good security practices while individuals have access to the facility. The concept of security culture ultimately stems from the broader theory of organizational culture, which argues that the dynamics of organizations can be described by the interactions between core beliefs (e.g., underlying assumptions), shared characteristics (e.g., espoused values), and observable behaviors (e.g., visible artifacts) (Schein 1990). In the nuclear security context, this emphasis shifts to perception of the existence of a credible threat and the belief that nuclear security is vital to combatting such threats. However, Cole et al. (2013) offer a review by human factor experts at Sandia National Laboratories that identified a range of interpretations for the term safety culture. While safety culture and security culture have different end goals, they face similar challenges in their implementation. To be successful in improving security culture, organizations should promote values such as awareness, reporting, flexibility, learning, and just practices.

In order for security culture to take hold there must be buy-in from senior leadership and management. While security culture can be influenced by the international community, national regulations and priorities, public support, norms, and threat credibility, it is ultimately manifested in management systems and employee behaviors. A badging system only works well when everyone has to wear a badge – including the president of the organization. Insider prevention is only as good as the security and security culture of an organization.

Protective Measures to Mitigate Insider Threats

Where preventative measures seek to ensure that a threat does not access a facility, *protective measures* initialize when preventative measures have failed – meaning that potential insiders have been granted authorized access. Protective measures are implemented to inhibit inappropriate access to sensitive facilities, materials, or information by those with authorized access to a subset of these assets. Similar to the objectives of physical security, the goals of protective measures are to detect, delay, and respond to malicious insider acts to mitigate or minimize negative consequences. Protective measures take place after individuals are granted regular access (e.g., after being hired), enhanced access (e.g., additional clearances are granted), and irregular access (e.g., once inspectors or visitors are on the premises). Two common protective strategies include

access control systems and employees reporting suspicious behavior.

Access control technologies are implemented to intentionally restrict proximity to (or contact with) sensitive facilities, materials, or information. In so doing, the protective measure distinguishes between who does (and who does not) have authorized access – a direct protection against potential insider threats. For example, access to a nuclear power plant's control room can range from visitors being escorted on tours to operators entering the room unescorted during business hours to power plant management with the authority to enter the control room during nonbusiness hours. In addition, access controls protect against the insider threat by helping facilities systematize and expedite decisions regarding who can appropriately access what locations, materials, or information with their facility. Access control technologies can include badge readers, biometrics, passwords, physical locks, pin code-based controls, or some combination of these technologies to ensure only trusted employees can access sensitive locations, information, and materials. Access control technologies, then, actively restrict – and account for – all individuals attempting to access sensitive assets to protect them against potential malicious insider acts.

While access control technologies provide enhanced protection against the insider threat, they are only effective if the databases and supporting digital infrastructure are themselves protected. If an insider can edit the access control database, they can allow themselves or others authorized access to any facility or location within it. Yet, protections on these databases and networks work in concert with traditional access controls in reinforcing dynamics to improve insider threat protection. There is a similarly high need for vigilance in individuals with access control responsibilities (including managing the related databases) to protect against insiders. Individual vigilance can be supported by organizational procedures (e.g., implementing the two-person rule for access or strict change management procedures) and improving security culture. Additionally, if an insider successfully executes a malicious act, access controls can be used forensically to support attribution of the malicious act. For example, badge reader data for a toxic chemical storage vault can help identify a disgruntled maintenance worker who poured a hazardous liquid into the facility's ventilation system.

As potential insiders know many of the technological protections in place, a second protective measure relates to employee observation of behavioral patterns to limit the ability for unauthorized access. Behavioral reporting programs are related to preventive measures (e.g., human reliability programs and nuclear security culture) but include more formalized protocols to stop the inappropriate access of sensitive facilities, materials, and information by individuals with authorized access. Like their technological counterparts, protective measures based on behavioral observations can become more stringent based on the sensitivity of facilities, materials, or information. For example, concerning political statements made by janitorial staff should not warrant the same level of potential concern as those same comments made by a chief scientific officer with unfettered facility access. In general, reporting of unusual or suspicious behavior should not lead immediately to disciplinary action, but rather to a comprehensive investigation to determine if an insider may have developed the motivation to carry out an attack.

In addition to requiring high-level support, organizations must consider behavioral reporting programs carefully. One major challenge behavioral reporting programs face is the potential conflict with social culture or personal feelings, where employees are reluctant to "betray" a friend/colleague or feel betrayed by those who reported them. Thus, success of these types of protective measures is based on employees feeling comfortable about reporting suspicious or unusual behaviors of their colleagues without fear of reprisal. In order to avoid some of the negative feelings that can arise from behavioral reporting programs, companies must have a clear definition of what "suspicious behaviors" are and when they expect their employees to report. Unclear definitions and guidelines can cause confusion and lead to frustration and anger. Finally, organizations must have timely and "fair" responses to indicators and behavioral reports – along with robust records to document the justification for their decisions. Example of "fair" responses to reports of

suspicious or unusual behaviors typically ranges from intensified monitoring to restrictions in job responsibilities to termination and even legal action.

Conclusion

Sustaining a high-performing insider threat mitigation strategy is challenged by the difficulty in achieving – and maintaining – high levels of human reliability surrounding sensitive facilities, materials, and information. One difficulty in human reliability is the conflict between high-quality insider threat initiatives (e.g., enhanced performance monitoring), legal/regulatory requirements, and individual privacy. Another difficulty is often posed by the underlying social culture, especially if cultural sensitivities tend toward a lack of trust in government (or non-familial authority), high levels of tribal loyalty, or an inherent trust of others. In addition, it is difficult to measure the effectiveness of insider threat mitigation programs, as proving that an insider attack did not happen *because* of a robust insider threat program is extremely challenging. Despite this, evidence suggests these programs have been successful in mitigating insider threats. To this end, Bunn and Sagan (2014) present ten lessons learned from past insider threat cases and declare the "main lesson of all these cases is: do not assume, always assess – and asses (and test) as realistically as possible" (p. 20).

The potential for insider threats poses an evolving, multifaceted set of challenges to the security of sensitive facilities, materials, or information. As discussed above, potential mitigation strategies must be similarly flexible, wide-ranging, and applied continuously throughout the period that individuals have (or are seeking) authorized access to sensitive assets. In response, the US National Insider Threat Task Force has published a set of best practices to help outline appropriate insider threat mitigation strategies (2016, 2017). These best practices include decide who should be engaged, determine what matters most to your organization, reassess personnel management practices, develop clear termination procedures, engage the workforce, review systems for security/vulnerability, engage your privacy experts, put information in context, and test your security posture. In addition to regular testing, insider threat mitigation strategies should be updated each time a significant challenge is identified. The need for vigilance and diligence in insider threat mitigation stresses "a dynamic effort requiring constant evaluation, fresh perspectives, and updated approaches" (NITTF 2017) to effectively detect, prevent, mitigate, and protect against insider threats.

Intelligence Community · Collection Disciplines · Intelligence Cycle

Definition

Intelligence is information that has been collected, processed, analyzed, and disseminated to policy and decision-makers at their direction to fulfilling their needs and provide knowledge or foreknowledge of issues of concern.

Introduction

When people hear the word intelligence in terms of national or homeland security, they often think that it is "nothing more than information that is secret, or relate it to covert action or espionage depicted in movies whose main characters are named James Bond or Jason Bourne" (Cozine 2015, p. 81). The reality is, especially in a post-September 11th world, intelligence is much more than secret information and spying, and what is seen in the movies and television is often far from reality. In fact, James Bond and Jason Bourne would make terrible intelligence officers because a successful intelligence officer is discreet and would not drive fancy sports cars while wearing a tuxedo or engage in hand to hand combat in a crowded market place (Cozine 2015). In the United States, while the Central Intelligence Agency (CIA) or the National Security Agency (NSA) are what that pop into people mind, but there are actually a number of other agencies that are part of the nation's Intelligence Community (IC), but there are actually a number of other agencies that are part of the nation's Intelligence Community (IC), as well as a host of federal agencies outside of the IC, state and local agencies, and increasingly the private sector that play a role as both "consumers" and "producers" of intelligence. Likewise, the sources of intelligence are not just spying on our adversaries but rather from various collection disciplines, each with their own unique sources and methods for gathering information. Given these common misconceptions about intelligence, the next section seeks to shed light on what intelligence really is.

What Is Intelligence?

According to Lowenthal (2020), a great deal of people think that intelligence is nothing more than information that is secret. However, "information is anything that can be known, regardless of how it was discovered." Intelligence, on the other hand, is information that meets the need of policy or decision-makers that has been collected, processed, and narrowed to meet those needs (Lowenthal 2020, p. 1) Intelligence, when it is disseminated, is often referred to as a "product" and those who it is produced for are "consumers" (FAS 1995). Just like any other commercial product that fills the needs or meets a market's demand, an intelligence product must also meet the demands of the consumer; thus, intelligence is consumer driven. Consumers anticipate that they will need information or have a question answered before planning a task or making a decision and they will charge an intelligence organization with providing the information or answering the question. This tasking is known as an intelligence requirement. It is then up to the intelligence organization to meet the needs of the consumer and fulfill the intelligence requirement. However,

intelligence is not about truth or a definitive answer as the analyst will almost never have the complete picture. The goal is to produce a product that is reliable, unbiased, and honest (Lowenthal 2020).

Intelligence allows its consumers, ranging from high-level policy-makers to frontline personnel to make decisions, take action, consider possible alternatives, and predict possible outcomes. Intelligence can consist of both classified and unclassified information (Lowenthal 2020). As Lowenthal (2020) stated, "[a]ll intelligence is information. . .[but] not all information is intelligence" (p. 1). Intelligence can be categorized as strategic, anticipatory (often referred to as tactical), and operational. Strategic intelligence "identifies and assesses the capabilities, activities, and intentions of states and non-state entities to develop a deep understanding of the strategic environment, warn of future developments on issues of enduring interest, and support U.S. national security policy and strategy decisions" (ODNI 2019b, p. 8) Anticipatory intelligence identifies and assesses "new, emerging trends, changing conditions, and underappreciated developments to challenge long-standing assumptions, encourage new perspectives, identify new opportunities, and provide warning of threats to U.S. interests" (ODNI 2019b, p. 9). The goal of current operational intelligence is to provide "timely intelligence support to enable planned and ongoing operations" (ODNI 2019b, p.10). Like war, intelligence has a long history, not just within the United States but around the world.

History of US Intelligence

Intelligence within the United States traces its roots back to the Revolutionary War. As the commander-in-chief of the Continental Army during the war, General George Washington knew how important intelligence was to the Continental Army and its ability to win the war. Intelligence was vital to the effort to defeat a more powerful, better-funded, and better-organized British army, the world's reigning superpower at the time. General Washington and the Continental Army "ran networks of agents and double agents; set up elaborate deceptions against the British army; coordinated sabotage operations and paramilitary raids; used codes and ciphers; and disseminated propaganda and disinformation to influence foreign governments" (Central Intelligence Agency 2007a). They even uncovered a traitor within their own ranks, the infamous Benedict Arnold. In the very first presidential State of the Union address, the now president of Washington requested that Congress establish a "secret service fund" for clandestine activities. "Under Washington's Presidency[,] intelligence spending was higher than at any time in the country's history amounting to 12 % of the national budget" (Central Intelligence Agency 2007a).

The importance placed on intelligence on a national level did not last much beyond the Washington Presidency. The reason is, especially after the War of 1812, the United States did not have a strong foreign policy interest beyond its borders. Up until World War II, intelligence operations, capacities, and organizations were piecemealed together as the United States found itself involved in conflicts at home and abroad. In fact, during the period between the War of 1812 and World War II, the United States had only one continuous intelligence organization, the Office of Naval Intelligence, which was established in1882 and remains the oldest intelligence organization in the nation. Overall, intelligence was seen as a law enforcement function focusing on domestic concerns, such as criminal enterprises, and preventing foreign intelligence operations and influence. The United States' ability to collect foreign intelligence eroded and it wasn't until Congress declared war on Germany in 1917 that the military received more resources to increase its intelligence capability. After the War, US abilities to collect foreign intelligence and conduct covert actions were greatly diminished as intelligence entities' budgets were substantially reduced (Central Intelligence Agency 2007a). This diminishing of the United States' intelligence capabilities all changed in the lead up to World War II. In 1941, when it seemed inevitable that the United States was going to end up involved in the conflict that President Roosevelt established the first

peacetime, independent intelligence agency, the Office of the Coordinator of Information. The Office of the Coordinator of Information was designed only to organize the activities of several agencies' intelligence functions, but the lack of intelligence that could have prevented the attack on Pearl Harbor shed light on the faults with this approach of simply coordinating intelligence activities. As a result, a larger and more diversified agency, the Office of Strategic Services (OSS), was established in 1942 to succeed the Coordinator of Information. The OSS is the forerunner of today's Central Intelligence Agency (2007a).

Following the War, as was the case throughout the nation's history, there was sentiment for the need to return to the normalcy of the pre-war military positioning and demobilization began. This included the abolishing of the OSS in October 1945 as the nation's only civilian intelligence agency. This demobilization did not last however, as the perceived threat of the Soviet Union and the looming Cold War, illustrated the the need for a centralized intelligence system, even in peacetime was recognized. In 1947, President Truman signed into law the National Security Act of 1947, representing the largest government reorganization in US history and establishing national security framework for the next half century. Among other things, the Act established Central Intelligence Agency (CIA) as an independent civilian intelligence organization with the Director of Central Intelligence as its head while also serving as head of the Intelligence Community and principal intelligence advisor to the National Security Council and the President. The CIA was charged with "coordinating the nation's intelligence activities and correlating, evaluating, and disseminating intelligence that affects national security," while also expressly prohibiting the CIA from having any "police, subpoena, law-enforcement powers, or internal security functions" (Central Intelligence Agency 2007b). Over the next 50 years, other intelligence organizations were established to provide for greater intelligence coverage leveraging new advancements in technology or emerging issues.

Traditionally, intelligence is thought of as a national security issue relating to defense and foreign policy. In the aftermath of the September 11th attacks, there was a realization that the threats and dangers the United States faced were not only from hostile nation-states but also from dangerous non-state actors, such as terrorist groups and transnational organized crime. As a result, there has been an increased emphasis placed on homeland or internal security, including the realization that local and state agencies mostly play a greater role in the nation's intelligence apparatus. The attacks were also perceived as a major intelligence failure. To address this intelligence failure, President George W. Bush signed into law, among other laws, the Intelligence Reform and Terrorism Prevention Act of 2004. Like the National Security Act of 1947, this Act represented a major overhaul of the nation's intelligence system. The Act established the cabinet-level position of the Director of National Intelligence, tasked with managing the National Intelligence Program (NIP), and replaced the DCI and the head of the IC. The Act also established and defined the concept of national intelligence which "includes information gathered in the United States or abroad that pertains to more than one agency and involves threats to the United States, its people, property, or interests; the development, proliferation, or use of weapons of mass destruction; or any other matter bearing on national or homeland security" (S. 2845 2004) National intelligence, therefore, bridges the foreign-domestic divide, includes a focus on homeland security as well as the traditional IC focus on foreign intelligence, and identifies the need for knowledge sharing among IC agencies in order to be utilized effectively. To create national intelligence for a diverse set of consumers, information needs to be collected, processed, analyzed, and narrowed to meet the specific needs of decision- and policy-makers.

Intelligence Collection

Intelligence collection is not new and the various ways that intelligence has been collected have developed over time. Its advancements in technology have ultimately led to new approaches for

intelligence to be collected leading to the development of five distinct principal methods to collect intelligence (i.e., collection disciplines). These collection disciplines are as follows:

1. Human-Source Intelligence (HUMINT). HUMINT refers to intelligence obtained from human sources and includes overt, clandestine, or covert activities and those individuals who exploit, manage, or support these activities. Overt HUMINT sources can include attaches and diplomatic personnel, official delegations, debriefing of refugees, and inmates in detention centers and prisons. Clandestine HUMINT sources are primarily agents who have been recruited by a case officer from an intelligence organization or have volunteered to provide information or infiltrate an organization to gather information or intelligence about a particular target (Cozine 2017). A Covert HUMINT source is one where the relationship between the agent and the sponsor will never be acknowledged. In these cases, the covert source will generally leave the country under the guise of being political refugees or need to be exfiltrated from the country (Althoff 2015).
2. Signals Intelligence (SIGINT). "*SIGINT* is derived from signal intercepts comprising – however transmitted – either individually or in combination: all communications intelligence (COMINT), electronic intelligence (ELINT) and foreign instrumentation signals intelligence (FISINT)" (ODNI 2019b). COMINT "includes information derived from intercepted communications transmissions. . . [and] targets "voice and teleprinter traffic, video, Morse code traffic, or even facsimile messages" (Nolte 2015, p. 81), while ELINT covers non-communications transmissions, such as radar that are intercepted and analyzed. FISINT, on the other hand, consists of "intercepts of telemetry from an opponent's weapons systems as they are being tested. Telemetry units provide designers with information on a prototype's guidance system operation, fuel usage, staging, and other parameters vital for understanding operational characteristics" (Nolte 2015, p. 98). SIGINT's roots can be traced back to World War I when the British successfully began intercepting German communications by tapping underwater cables. Today, it is collected by a variety of Earth-based methods, such as ships, planes, and ground sites or from space by satellites. An advantage of SIGINT is that it provides insight into what is being said, planned, or considered by reading messages and determining meaning through content analysis. A disadvantage of SIGINT is that targets of collection efforts can use encryption devices in order to conceal the content of their communications or can use false transmissions to conceal their true intentions (Lowenthal 2020).
3. Geospatial Intelligence (GEOINT). GEOINT refers to "the exploitation and analysis of imagery and geospatial information to describe, assess, and visually depict physical features and geographically referenced activities on the earth. Geospatial intelligence consists of imagery, imagery intelligence, and geospatial information" (National System for Geospatial Intelligence 2018, p. 3). Geospatial information can be more readily defined as "data, information, and knowledge gathered about entities that can be referenced to a particular location on, above, or below the earth's surface" (Murdock and Clark 2015, p. 111). GEOINT combines an image with intelligence and geospatial information about the location of the image to try to determine what the image means in terms of a specific intelligence requirement. Imagery is usually in the form of photographs, but it can also include other types of images such as infrared imagery or spectral analysis that measures changes in the reflections of certain rays of light within the spectrum. One of the big advantages of GEOINT is that it is easy to understand and interpret. A major disadvantage is it is only a snapshot or a photograph of a particular place at a particular time and that it is susceptible to denial and deception techniques, such as using camouflage or the avoidance of engaging in illicit activities during satellite passes (Lowenthal 2020).

4. Measurement and Signature Intelligence (MASINT). MASINT is "scientific and technical intelligence information obtained by quantitative and qualitative analysis of data" that "enables detection, location, tracking, identification and description of the unique characteristic of fixed and dynamic target sources". It employs "a broad group of disciplines including nuclear, optical, radio frequency, acoustics, seismic, and materials sciences" (ODNI 2019b). MASINT is used to identify gases or waste leaving factories or other facilities, indications of nuclear development, and other specific characteristics or materials related to the development of weapons systems and the development of WMDs by both state and non-state actors. MASINT has six distinct sub-disciplines: (a) electro-optical, which measures the properties emitted or reflected from the various types of light including both visible and non-visible light; (b) geophysical, which measures disturbances and anomalies on physical fields on the surface of the Earth, such as acoustics, gravity, and magnetic and seismic activities; (c) material, which measures the composition and identifies various gases, liquids, and solids; (d) nuclear, that measures the quantities and qualities of nuclear signature, such as gamma rays, X-rays, and neutrons; (e) radar, which measures the properties of radio waves reflected from targets or objects; (f) and radio frequency, which measures the electromagnetic signals generated by an object and its various band widths (Morris and Clark 2015). One of MASINT's biggest advantages is that it is difficult for collection targets to implement denial and deception countermeasures because of the scientific nature of the discipline. For example, it would be difficult to conceal or alter the heat signature of certain types of weapons. However, the scientific and technical nature is sometimes a disadvantage too as MASINT is not appreciated or easily understood by some intelligence consumers, especially policy-makers (Lowenthal 2020).
5. Open-Source Intelligence (OSINT). OSINT is "publicly available information appearing in print or electronic form including radio, television, newspapers, journals, the Internet, commercial databases, and videos, graphics, and drawings" (ODNI 2019b). OSINT is defined by the National Defense Authorization Act of 2006 as "information that is publicly available to any one through legal means, including request, observation or purchase, that is subsequently acquired, vetted and analyzed, in order to fulfill an intelligence requirement" (Jardine 2015, p. 6). Publicly available means the information is available to any member of the general public. Available information is not necessarily free; it could be accessed and/or obtained with purchase. It cannot be obtained through any act of trespassing, theft, hacking, or use of social engineering, all of which would be illegal, and it also means that it cannot be considered publicly available. It must be vetted and analyzed to appraise, verify, or check for accuracy, authenticity, and validity. Finally, it must fulfill an intelligence requirement of a consumer (Jardine 2015). The advantage of OSINT is that it is readily available and is an excellent starting point for all other collection efforts. OSINT can assist framing a problem, quickly establish what is known through open sources, where intelligence gaps exist, and where other INTs must try and fill in the missing pieces. The major disadvantages include (but are not limited to) the following: sheer amount of data is available from open sources, reliability of sources is unknown, and public data may be intentionally manipulated or taken out of contexts (Lowenthal 2020).

The Intelligence Cycle

As stated earlier, intelligence is much more than simply collecting information or data. Intelligence is an entire process used to create a finished intelligence product to meet the specific needs of policy-makers. The process by which this is achieved is known as the intelligence cycle, a five-step process made up of planning and direction, collection, processing, analysis and production, and dissemination. The process is called a cycle

because it is circular in nature. An intelligence product may lead to new questions and the need for new intelligence. The process can become never-ending progression of developing intelligence for as long as consumers needs for intelligence on a specific topic exist. There are checks and balances at each stage of the process that must be completed before moving on to the next step in order to ensure that reliable and accurate intelligence is created. While this view sometimes oversimplifies what actually occurs, it is a useful construct for understanding the basic functions that any intelligence enterprise must accomplish to be successful.

The first step of the intelligence cycle is planning and direction, which begins when policymakers or other decision-makers express a need for intelligence information. This need for intelligence information is referred to as an intelligence requirement. This requirement is passed to an intelligence agency, where an answer is developed and then disseminated to thee requesting policymaker (Lowenthal 2020). Today's threat environment represents an endless and complex array of information, making it infeasible for intelligence agencies with limited resources to cover every possible threat with equal attention. As a result, some issues and targets will receive top priority; others will only receive peripheral attention, while still others will receive little if any notice. The challenge is setting requirements that dictate which issues or targets receive highest priority. In short, it is about establishing what issues are of greatest importance and what data must be collected and analyzed to provide the best possible answers. Within the US intelligence framework at the federal level, it is "policy-makers, including the president, his or her advisers, the National Security Council, and other major departments and agencies of government, initiate requests for intelligence" (ODNI 2019b). The issue coordinators within the IC interact with these policy-makers to identify core concerns and requirements. It is the formulation, establishment, and evaluation of these intelligence requirements that is an important element of starting the intelligence cycle and pointing it in the right direction. If priorities and resources are misallocated, chances are greater that collectors will overlook important information that cannot then contribute to subsequent stages of the intelligence process (Lahneman 2017).

The next step of the process is collection. In response to the established intelligence requirements, an intelligence agency develops an intelligence collection plan. This plan evaluates available sources and methods already available within their own organization and may also seek intelligence from other agencies. After this existing intelligence is considered, a determination is made to see what additional information or data need to be collected to fulfill that requirement. These additional needs are usually referred to as a collection requirement (ODNI 2019b). To fulfill collection requirements, decisions have to be made on how to acquire the required information, what assets are in place to collect it, where to collect it, when to collect it, and then physically acquiring the information. As discussed in the previous section, depending on the agency and its capabilities, sources may include HUMINT, GEOINT, MASINT, SIGINT, and OSINT. These methods of collection share one major commonality: they are all resource intensive. Launching satellites, intercepting signals, and running agent networks are all costly. Accordingly, managers of the different collection disciplines compete for limited budgetary resources (Lowenthal 2020). The information that is acquired during the collection phase and forwarded on to the next step of the cycle is known as raw intelligence.

Collection systems accumulate vast quantities of information, of which only a fraction is usable. Not only must the relevant information be identified and separated, but it must also be repackaged in accessible ways. This need to repackage the data gives rise to the processing and exploitation phase of the intelligence cycle. This phase is where raw data is turned into a form usable for analysis. Skilled specialists must sift through collected information in search of useful intelligence. The techniques used in filtering information include "exploiting imagery, decoding messages and translating broadcasts, reducing telemetry to meaningful measures, preparing information for computer processing, storage and retrieval,

placing human-source reports into a form and context to make them more understandable" (ODNI 2019b). For example, photo-satellites capture thousands of images across the planet, all varying in terms of resolution, angles, daylight, and weather conditions. To the untrained eye, all these variations could mean nothing, but professionals who have expertise in imagery are able to screen each image for subtle clues and indicators that might suggest an important finding. Similarly, other intelligence professionals such as code breakers, translators, and weapons experts use their own expertise to sift out the most relevant information (Lahneman 2017). At the end of the processing and exploitation stage, raw intelligence is passed on to the next phase for analysis and production.

During the analysis and production stage, raw intelligence is integrated, evaluated, and analyzed for the preparation of intelligence products that seek to fulfill the intelligence requirements transmitted by the consumer. Analysis is considered to be the most important part of the intelligence cycle because it is where information is converted into finished intelligence. For this reason, analysts are often considered the most important persons within the intelligence cycle. Analysts are specially trained employees of intelligence organizations who typically combine substantive expertise in a variety of issues to "integrate data into a coherent whole, put the evaluated information in context, and produce finished intelligence that includes assessments of events and judgments about the implications" (FAS 1995). Analysts rely on their keen analytic capacities and strong written and oral communication skills to achieve this function successfully. In short, their job is to assemble many different pieces of collected and processed information, evaluate this information in terms of their specialized knowledge, consider its implications for security and policy interests, and succinctly disseminate these judgments in written and oral formats as appropriate.

Dissemination, the last stage of the intelligence cycle, refers to the distribution of intelligence products to the policy-makers who requested them. After information is collected, combined with data from other possible sources, organized, and analyzed to create finished intelligence, it can be disseminated directly to the same policy-makers whose initial needs generated the intelligence requirements. Dissemination is all about getting the right intelligence to the right people at the right time. It is a rigorous job that represents the sum efforts of all previous stages combined. The Office of the Director of National Intelligence (2019b) identifies five categories of finished intelligence:

> "current intelligence, that addresses day-to-day events; estimative intelligence, that looks forward to assess potential developments that could affect U.S. national security: warning intelligence, that sounds an alarm or gives notice to policy-makers; scientific and technical intelligence, that includes an examination of the technical development, characteristics, performance and capabilities of foreign technologies, including weapon systems or subsystems; research intelligence, that supports other finished intelligence products (p. 7)."

Most intelligence consumers are inundated with a constant barrage of competing information and intelligence reports. These reports may constitute only a fraction of the documents they receive. As a result, intelligence professionals must find ways to customize reports for different types of consumers and put them together in ways that convey the most important information in the least demanding fashion (Lahneman 2017).

While dissemination of finished intelligence represents the last step of the intelligence cycle, it does not represent the end of the intelligence process. Despite the best collection and analytical efforts, intelligence does not exist until consumers acknowledge it, understand it, and then make decisions based on this intelligence. When an intelligence product is disseminated, it is often taken for granted that policy-makers will digest and act upon the intelligence they receive, but this outcome is by no means guaranteed. When the consumer does review and hopefully use finished intelligence, they will often provide feedback to the intelligence producers. Feedback is when consumers evaluate the intelligence organization's performance on any of the parts of the intelligence cycle and provide recommendations for future improvement. Additionally, after intelligence is disseminated, the consumer may provide

feedback in the form of more questions to be answered or a request for more information. These requests results in the creation of new direction and intelligence requirements being established. These new requirements return to the planning and direction stage starting the cycle over again.

Who Creates Intelligence?

The intelligence process refers to the process of how intelligence is created, but who is responsible for producing it. At the federal level, it is the intelligence community that serves as the primary intelligence apparatus of the nation. As mentioned earlier in this chapter, the National Security Act of 1947 laid the foundation of the United States' modern security infrastructure, and in doing so, it structured a cooperative framework known as the intelligence community (IC). The goal of the IC is to unite and coordinate the formerly disparate intelligence agencies. The core mission of the IC has remained to "work separately and together to conduct intelligence activities necessary for the conduct of foreign relations and the protection of the national security of the United States" (Office of Naval Intelligence n.d.). Currently, the IC is composed of seventeen separate agencies. The IC draws its membership from five executive branch departments and one independent agency. These agencies perform a variety of intelligence and counterintelligence functions and report to different civilian and military clients. The IC is accountable to a Director of National Intelligence who tasked with overseeing the operations of the entire IC. The IC's current structure evolved piecemeal as a result of Cold War, developments and advances in technology, the intricacy of the intelligence process and the presence of many different intelligence consumers. It is these consumeers, with widely different requirements, that dictate the structure of the US national intelligence apparatus.

Eight out of the seventeen agencies of the US IC are located in the Department of Defense (DOD) and it administers an estimated 80% of the entire intelligence budget. Each agency has its own director that oversees its operation; they are all ultimately accountable to the Under Secretary of Defense for Intelligence, and through this official, to the Secretary of Defense (Lowenthal 2020). Within DOD, there are four agencies that are members of the IC: the National Security Agency (NSA), National Geospatial-Intelligence Agency (NGA), National Reconnaissance Office (NRO), and the Defense Intelligence Agency (DIA).

The NSA has a three-pronged mission. First, it functions as the IC's primary collector of SIGINT. The SIGINT mission is to collect, process, and disseminate intelligence derived from foreign communication, electronic, and instrument signals for intelligence and counterintelligence purposes, as well as to support for military operations. Second, it is responsible for information assurance (IA) in which the NSA attempts to prevent foreign intelligence agencies and other adversaries from gaining access to sensitive or classified national security information and collecting intelligence. Third, is the Central Security Service (CSS) that provides cryptologic support to the intelligence community and military. The NGA provides GEOINT to a wide array of policy-makers, military commanders, and intelligence professionals, as well as first responders and others involved in disaster management. The NRO is in charge of designing, building, launching, and maintaining America's intelligence satellites. The DIA, established in 1961 to centralize the intelligence received by the service branch agencies, provides "military intelligence to warfighters, defense policy-makers and force planners in the Department of Defense and the Intelligence Community in support of U.S. military planning and operations, and weapon systems acquisition" (DIA n.d.). Each branch of the armed forces within DOD (Army, Navy, Air Force, and Marine Corps) maintains its own intelligence organization to support the mission effectiveness of its respective service.

In addition to those members of the IC that are within DOD, there are also seven IC members that are considered departmental intelligence organizations in that they are houses within a cabinet-level department and report to the head of that department who are their primary consumers. The State Department's Bureau of Intelligence

and Research's (INR) primary mission is to produce intelligence products to support US diplomat efforts by providing independent analysis of events to the state department policy-makers to support foreign policy and national security efforts within the department. The Department of Energy's (DOE) Office of Intelligence and Counterintelligence is responsible for protecting vital scientific and technological national security information and providing scientific and technological expertise in support of policy-makers. The Department of the Treasury's (DOT) Office of Intelligence and Analysis (OIA) mission is to deliver timely, accurate, and relevant intelligence to decision-makers to protect financial integrity of the country by assessing and identifying threats and vulnerabilities into the nation's financial infrastructure. There are two organizations that are within the Department of Justice (DOJ) that are members of the IC. The Federal Bureau of Investigation (FBI) not only serves as an investigative law enforcement agency but also collects and produces intelligence to support its own investigations and creates products that support partner agencies and help those agencies to better understand and face the security threats the nation faces domestically. Likewise, the Drug Enforcement Administration (DEA) has a dual law enforcement and intelligence responsibility. The DEA's Intelligence Program initiates new investigations into violations of controlled substance laws and major drug organizations, support ongoing investigations, and provide policy-makers with intelligence products related to drug trend information. Like DOJ, the Department of Homeland Security (DHS) also has two components that are members of the IC. DHS's Office of Intelligence and Analysis (I&A) mandate is to equip its federal, state, and local partners as well as certain components of the private sector with the timely intelligence and information to assist them in keeping the homeland safe and secure. I&A serves as a conduit between the IC and the Homeland Security Enterprise to deliver intelligence to enterprise partners and to develop intelligence received from those partners for use by DHS and the IC. Also within DHS, the US Coast Guard Intelligence (CG-2) in the organization's unit was tasked with developing strategic, tactical, and operational intelligence related to the safety and security of the maritime domain, to support missions, and to inform decision-makers both within the Coast Guard and the Homeland Security Enterprise when developing policy with ramifications for maritime and port security.

The Central Intelligence Agency (CIA) is the agency that first comes to mind for most people when they think of the IC. The CIA is both a collection and an analytic agency and plays the leading and coordinating role in the collection of human intelligence or HUMINT.

Additionally, the CIA is the only intelligence agency authorized to carry out covert operations in foreign countries. The CIA is an independent agency, which, unlike the rest of the IC, is not subordinate to a cabinet official but rather accountable to the Director of National Intelligence, the National Security Council, and the president. This unique arrangement is a direct product of the National Security Act of 1947. The CIA is organized into five different directorates: the Directorate of Operations (DO), the Directorate of Analysis (DA), the Directorate of Science & Technology (DST), the Directorate of Support (DS), and the Directorate of Digital Innovation (DDI). The DO is arm of the CIA responsible for the coordination of covert operations and clandestine human intelligence collection across the IC. The DA uses information collected by the DO and other IC partners to analyze, produce, and disseminate all-source intelligence products on a wide variety of national security and foreign policy issues to consumers across the US government. Created in 2015, the DDI is the CIA's newest Directorate focusing on developing and implementing cutting-edge digital and cyber tradecraft and maintaining the agency's IT infrastructure (Central Intelligence Agency 2015).

Intelligence Sharing Within and Beyond the IC

There are also varieties of agencies at the federal level outside of the IC that have intelligence components. For example, in DHS alone, there is US Customs and Border Protection's (CBP) Office of Intelligence, Immigration and Customs

Enforcement (ICE) Office of Intelligence, and the Transportation Security Administration's (TSA) Office of Intelligence and Analysis (OIA) (to name a few). CBP's Office of Intelligence supports CBP's mission by providing intelligence in support or field operational capability, as well as strategic analysis focusing on terrorist, geopolitical, and economic threats to the agency's leadership, to aid in decision-making. ICE's Office of Intelligence (aka HSI-Intel) analyzes, produces, and disseminates strategic and tactical intelligence products to the agency's operational elements and leadership. The focus of these products includes identifying smuggling patterns, techniques and routes, and trends in criminal activity and predicting emerging and future threats. TSA's Office of Intelligence and Analysis (OIA) identifies security risks to prevent attacks against the US transportation system for a wide range of consumers (Cozine 2016).

Especially after September 11th, state and local law enforcement agencies began to take on a larger role as both producers and consumers of intelligence. Federal authorities became increasingly dependent on state and local agencies, and to a certain extent, private citizens to be their eyes and ears on the street and also their boots on the ground to carry out certain actions. Procedures had to be established in order to drive the intelligence collection, processing, and develop the intelligence communication systems of state and local agencies. Decision-makers at the state and local levels, and to a certain extent the private sector, also have become consumers of intelligence generated at the federal level. This dual role of state and local agencies as consumers and producers of intelligence presented a difficult problem – how can raw intelligence from all these diverse sources be collected, processed, analyzed, produced and disseminated in a timely manner? It quickly became apparent that the existence of effective intelligence fusion centers at the regional, state, and local levels of government was necessary for achieving this goal.

In this newfound role as both consumers and producers of intelligence, state and local agencies and various federal agencies outside the IC discovered a need to be able to share intelligence among both themselves and the IC itself. However, the sharing of intelligence among agencies, even within the IC, has a long history of being problematic. While the secrecy of intelligence, and the need to protect sources and methods of intelligence collection, certainly plays a role, another major issue that hampers intelligence sharing is that intelligence is often thought of as a commodity that has value and should be horded rather than shared. Intelligence agencies can often act as silos of intelligence and even within intelligence agencies separate silos may exist. This lack of intelligence sharing prevents those who may make the best use of available intelligence from receiving it. Even across and within law enforcement agencies, those in possession of valuable intelligence and information will hold onto it in hopes of getting a major arrest and all the notoriety that goes along with it.

Following the September 11th attacks, the 9/11 Commission (2004) concluded that the IC failed to connect the dots about al-Qaeda's plan to attack the United States by turning commercial airliners into weapons of mass destruction because pieces of information pointing to the plot were held by various agencies that, in hindsight, if connected, could have prevented it. This problem was compounded by the fact that there are a variety of agencies at the federal level that were not members of the IC but held important information. One example is the cases of two of the September 11 hijackers, Khalid al-Mihdhar and Nawaf al-Hazmi. In early 2000, the CIA developed information that Mihdhar was a suspected al-Qaeda operative and he was previously issued a multiple-entry US visa. This intelligence was not shared with the US State Department, US Immigration and Naturalization Service (INS), and the US Customs Service (USCS). In late January 2000, Mihdhar and Hazmi both arrived in the United States and were allowed to enter the United States because the INS was not informed of Mihdar's terrorist connections. In late December 2000, the CIA and FBI developed information that connected Hazmi and Mihdhar with the man believed to be the mastermind of the US Cole attack in Yemen. Having left in June 2000, Mihdhar applied for and received a new visa in June 2001 and was allowed to enter the United States in July 2001 because both the State

Department and the INS were still unaware of his terrorist connections. It was not until August 23 that the CIA informed the State Department, FBI, INS, and USCS of the situation and recommended that Mihdhar and Hazmi be added to the watchlist databases as suspected terrorists. The FBI, upon learning of Mihdhar's entry on July 4, began searching for him in early September 2001 (Office of the Inspector General 2004). They did not share this information with any other federal, state, or local law enforcement agencies. These are just a few examples of how the lack of intelligence sharing hampered the ability of agencies to connect the dots of the attack on 9/11.

In its report, the 9/11 Commission stressed the need for all-source analysis across agencies because it is not possible to connect the dots without interagency cooperation. Likewise, there needed to be a better way to combined intelligence gathered overseas with information gathered domestically. The Commission also concluded that while the government has access to vast amounts of information and data, there lacked an effective system for processing and using it. The commission stated that the case of Mihdar and Hazmi demonstrated a system that requires a "need to know" before sharing. The Commission recommended information procedures be established to "provide incentives for sharing, to restore a better balance between security and shared knowledge and move from a culture of need-to know to a culture of need-to-share" (9–11 Commission 2004).

The concept of need-to-share was codified into law with the signing of the Intelligence Reform and Terrorism Prevention Act (IRATPA) of 2004, which also established the Information Sharing Environment (ISE) to facilitate the sharing of terrorist information. With the passage of the Implementing Recommendations of the 9/11 Commission Act in 2007, homeland security and weapons of mass destruction information were added to the ISE's portfolio. The mission of the ISE is to "[a]dvance responsible information sharing to further counterterrorism, homeland security, and counter weapons of mass destruction missions. Improve nationwide decision-making by transforming from information ownership to stewardship. Promote partnerships across federal, state, local, and tribal governments, the private sector, and internationally" (Office of the Director of National Intelligence 2019b).

One strategy that has been developed to link these potential sources together while simultaneously building the intelligence capacity of the fragmented US law enforcement community is the establishment of National Network of Fusion Centers. Intelligence fusion centers form a vital link between the federal intelligence community and state, local, and tribal levels of government. Fusion centers "are owned and operated by state and local entities with support from federal partners in the form of deployed personnel, training, technical assistance, exercise support, security clearances, connectivity to federal systems, technology, and grant funding" (Department of Homeland Security 2018). Their areas of responsibility vary. Some are operated by states, others by large cities, and still others have a regional focus. Intelligence fusion centers also operate in different ways. Some fusion centers run 24/7, while others operate for only one or two shifts per day. The goal of fusion centers is to:

> [e]mpower front-line law enforcement, public safety, fire service, emergency response, public health, critical infrastructure protection, and private sector security personnel to understand local implications of national intelligence, thus enabling local officials to better protect their communities. Provide interdisciplinary expertise and situational awareness to inform decision-making at all levels of government. Conduct analysis and facilitate information sharing while assisting law enforcement and homeland security partners in preventing, protecting against, and responding to crime and terrorism. (Department of Homeland Security 2018)

The need for intelligence sharing gets crowded even further when one considers the role of the private sector not just in the collection of intelligence but also as a potential consumer of intelligence. This need for intellignece sharing with the provate sector is greatest for those organizations involved in critical infrastructure protection as they are a highvalue target because if made incapacitated the effect would be devastating the overall health of the nation, particular if the effects of an attack cascaded to other areas within that sector or other sectors of critical infrastructure. At the heart of private sector intelligence sharing

regarding critical infrastructure are Information Sharing and Analysis Centers (ISACs). ISACs were established in 1998 to assist critical infrastructure owners and operators protect their facilities, personnel, and customers from a variety of threats and hazards by collecting, analyzing, and disseminating threat information to their members. ISACs are private organizations run by the owners and operators of critical infrastructure with the assistance and support of various federal, state, and local agencies. There are currently 21 sector-specific ISACs around the United States (National Council of ISACs 2019).

Conclusion

Intelligence allows its consumers, ranging from high-level policy-makers to frontline personnel, to make decisions, take action, consider possible alternatives, and predict possible outcomes.

The information needed to generate intelligence is collected through a variety of sources and methods within the five collection disciplines of HUMINT, OSINT, MASINT, GEOINT, and SIGINT. It is the intelligence cycle that is the process used to move from intelligence requirements set by the consumer to the finished intelligence that is produced and disseminated to the consumer to attempt to fulfill those requirements. The steps in this process include planning and direction; collection, processing, and exploitation; analysis and production; and dissemination. This methodical approach to creating intelligence to aid leaders and other decision-makers traces it root back to Sun Tzu and the *Art of War* and has been employed in the United States since the days of George Washington and the Revolutionary War. The approach to intelligence has evolved throughout US history as the threats faced by the nation change. It is likely that intelligence will continue to evolve as new threat emerge and the security environment changes.

Definition

The Internet is a global computer network that interconnects over 23 billion digital devices (Statista 2018).

Introduction

Originally intended to interconnect just a few hundred mainframe computers in universities and corporate and government labs, the Internet now enables desktops, laptops, cell phones, and just about anything that contains a processor to access information or connect with other devices anywhere in the world. Often categorized as the Internet of Things (IoT), in recent years billions of devices such as consumer appliances, sensors, and even medical devices have been connecting to the Internet. These devices soon will outnumber computers (Tung 2017a). Estimates show that by 2020 there will be four devices connected to the Internet for every person on Earth (Tung 2017b).

The Internet is, however, much more than a physical global network for interconnecting devices. The Internet also provides the essential services that allow software applications and devices to function together and exchange information reliably. Internet communication protocols have allowed developers to produce the Internet applications upon which we now rely: the web, search engines, social networks, and many other web applications. Services include an addressing and naming system so devices can locate each other, mechanisms for reliable transmission of information over what is essentially an unreliable, best effort delivery network, and even mechanisms for ensuring that information stored in different formats on different devices can be interchanged. Without such services, applications such as the World Wide Web would not exist.

Internet History and Development

Much of the underlying Internet technology was developed over 30 years ago in several US government-funded projects (Leiner 1997). In the 1960s and 1970s, the Defense Advanced Research

Projects Agency funded the initial prototype network known as the ARPANET, an effort to connect multiple heterogeneous networks through a system of gateway computers. In 1983, the ARPANET made the transmission control protocol/Internet protocol (TCP/IP) the standard communication protocols used in the network. Thus hosts and networks that made used TCP/IP standards could be added to the ARPANET.

In the mid-1980s, the National Science Foundation played a key role with its funding of NSFNET whose purpose was to interconnect supercomputing facilities at government laboratories and universities (National Science Foundation 2018). This project led to the development of a backbone network for the Internet and demonstrated its utility. The program paved the way for the transition to current model where private telecommunication companies provide most of the Internet network infrastructure and the service fees they charge finance infrastructure maintenance and development.

Today the Internet is a complex system of interconnected networks mostly owned by private sector telecommunication companies known as Internet Service Providers (ISPs). In some countries the networks are government owned and controlled. There are local and regional service providers as well as core service providers who interconnect regional providers and offer a type of backbone for the Internet. Moreover, in recent years, major content providers such as Google have developed their own global networks separate from the public Internet to interconnect their data centers. These content provider networks connect to ISPs to access the public Internet and attempt to avoid using the Internet core where possible. Typically, they rely on the public Internet to reach end users (Google 2018).

Internet Technology

The Internet designers introduced a number of network technologies and made a number of technical decisions that have allowed the Internet to scale from a few hundred machines to billions of devices (Leiner 1997). One key technology was the packet-switched network. In such networks, a large file to be transmitted, for example, is broken into multiple packets which are then transmitted over the network and reassembled at the destination. Packets may not even follow the same path from source to destination. A second crucial idea was to keep the complexity and computation at the end points. Most processing involved in moving traffic is done at the sending and receiving end points, with minimal processing on gateway devices that move traffic through the network. This was a departure from the way telecommunications worked at the time where if a sender and receiver wanted to communicate, intermediate switches had to be configured to make the connection. A third key component was the Internet addressing and routing systems that allowed networks to be added to the Internet with minimal impact on the existing system.

Of course, the Internet has benefited from the incredible increase in computational powered realized during the past 30 years. The switches and routers, key building blocks that move traffic, have increased in speed by at least three orders of magnitude during this period. Nonetheless the decision to keep processing on intermediate switching/routing devices to a minimum is a key factor in the scalability of the network. In addition, separating the physical network layer from other network layers allowed the massive investment in software applications at the network, and transport and application layers of the network to remain in place as underlying network hardware technologies evolved and improved.

From the beginning the technical specifications have largely been in the hands of committees of stakeholders who work together to devise the open or publicly available communication protocols and specifications needed to make the Internet work. With open protocols talented programmers anywhere in the world could develop network services and applications and improve on existing software.

Internet Management and Governance

Governance of a valuable shared resource such as the Internet, a critical information infrastructure for commercial activity and many competing

interests, requires technical standards as well as policies needed to address issues such as privacy, security, and access (Global Commission on Internet Governance n.d.). As a global system, the Internet has no central manager or authority. Each nation oversees the activities that take place on the Internet in that country – some are very open, while others are highly regulated. In addition, the private sector plays a key role through user terms of service agreements both for Internet access and use of various web applications. From the beginning, technical standards have followed the multi-stakeholder approach, a distributed form of governance that includes developers, users, and others with an interest.

The Internet Society (Internet Society 2018) is the umbrella organization that provides a home for and financial support for the Internet standards process. Two organizations manage the actual development of technical standards, the Internet Engineering Task Force (IETF), which oversees the development of detailed technical protocol standards, and the Internet Architecture Board (IAB), which considers the longer-term development of the Internet. The IETF publishes a set of technical protocol standards called Requests for Comments (RFPs) which define the standards for communication protocols and many Internet applications (IETF 2018). Another key organization, the Internet Corporation for Assigned Names and Numbers (ICANN), manages the Internet/Domain Name System, which provides names and addresses for Internet computers and services (ICANN 2018).

Two contentious Internet governance issues concern access and privacy. The net neutrality debate centers on the ability of an ISP to prioritize Internet traffic and provide higher levels of service for customers willing to pay for it. The fear is that customers who cannot afford a premium service will receive a lower level of service and be denied the full utility of the Internet. The European Union supports net neutrality (European Commission 2018a), while the Federal Communications Commission in the USA recently started allowing ISPs to charge more for preferred services. The issue of ISPs making use of customer data is being addressed by a number of states in the USA with some states passing legislation to restrict ISPs from accessing customer data without their explicit permission (National Conference of State Legislatures 2018). The European Union has a strict privacy regime which regulates the way ISPs and Internet search and social network companies handle user data (European Commission May 23, 2018b).

Deep and Dark Web

The deep web and the dark web characterize portions of the World Wide Web. Many conflate the two terms, but there is a distinct difference. Many consider the dark web to be a subset of the deep web. Both terms refer to web sites not generally accessible to search engines. Access to dark web sites requires special software which protects the anonymity of the both the web site and the browser computer. Web sites readily accessible to search engines and indexed by them are often referred to as being part of the Surface Web, which most estimates put at under 5% of the entire World Wide Web.

The deep web includes web pages that cannot readily be accessed by search engine web crawlers. Thus such pages are not indexed and won't appear in a list of search results. Examples of such pages include those protected by captchas, pages that require a user login, pages returned when one fills out a form, or paywall-protected digital media content.

Access to dark web sites typically requires the use of the Tor browser (TOR 2018). This browser makes it very difficult for someone monitoring a network to identify the address of either the browser or the web site being accessed. TOR often is used to browse the Surface and deep web as well when anonymity is desired. Dark web users often take the extra precaution of using a virtual private network for additional assurance of anonymity.

Dark web sites don't use extensions such as .org or .com but .onion, which is not part of the Internet/Domain Name System. Sites available on the Surface Web provide lists of sites in the dark web. The anonymity afforded by the dark web makes it widely used for nefarious activities including black markets, botnet operations, selling hacking services and malware, and a range of

criminal activities. In addition, dark net sites also host whistleblowing forums and political discussion groups that might be suppressed in certain countries.

Conclusion

The Internet and the applications it supports are critical to economic and social activities throughout the world. As an indication of how much the world has grown to rely on the Internet as an information source, Google currently processes over 3.5 billion searches each day up from about 3.5 million per day when it was founded in 1998 (Internet Live Stats 2018). In less than a generation, Internet-based applications such as social networks, search engines, online shopping and advertising, e-mail, and other applications have created entirely new industries and changed the way organizations and people interact and get information. A key challenge now is the governance of this shared resource so it continues to spawn innovation and development and at the same time protects the security of its users and makes the Internet work for everyone (Internet Society 2017).

Internet of Things

Marie-Helen Maras
Department of Security, Fire, and Emergency Management, John Jay College of Criminal Justice, City University of New York, New York, NY, USA

Keywords
Internet of Things · Privacy · Security

Definition

The Internet of Things (IoT) is an umbrella term used to describe a network of Internet-connected devices that collect, store, collate, analyze, and share a significant amount of information and monitor people, animals, plants, and/or objects in order to provide users of these devices with some form of service.

Introduction

The Internet of Things (IoT) is an umbrella term used to describe a network of Internet-connected devices that are designed to provide users of these devices with some form of service. In order to provide this service, these devices collect vast quantities of data about users and contextual data from these devices, and process, aggregate, and analyze this data. The data collected and processed is known as *big data*, "extremely large data sets that can be analyzed to reveal patterns, trends and associations, especially relating to human behavior and interactions" (Maras and Wandt 2019, p. 162). The contextual information from these devices is obtained through the real-time, continuous, and remote monitoring of everyday objects, plants, animals, and/or people (Maras 2015). The contextual information obtained from IoT devices enables them to make decisions independent of the users. An example of such a device is Amazon's Dash Smart Shelf, which identifies drops in the weight of supplies on the shelves and automatically reorders the supplies that need replenishing from Amazon (Haselton 2019). Ultimately, the Internet of Things, as envisioned, will consist of Internet-connected devices that, like Amazon Dash, will be able to make decisions primarily independent of any user input and predominately without the need for user input.

Security and Privacy Concerns

IoT devices were built with efficiency in mind and not security (Maras 2015). There are security risks associated with the use of this technology. The devices are vulnerable to unauthorized access and modification of features and services provided through hacking, and often include hard-coded passwords and backdoors that can be exploited by cybercriminals (Maras 2015). In the United States, there is currently no federal regulation of IoT devices. States, like California and Oregon, however, have passed legislation requiring manufacturers to include security features in IoT devices. For instance, California's 2019 law (Senate Bill No. 327) requires manufacturers "to equip the device with a reasonable security feature or features that are appropriate to the nature and function of the device, appropriate to the information it may collect, contain, or transmit, and designed to protect the device and any information contained therein from unauthorized access, destruction, use, modification, or disclosure." In the European Union, a law was passed, the EU Cybersecurity Act of 2019, that, among other things, called for establishing a cybersecurity certification framework in the EU for digital technologies (see EU Regulation 2019/881). This law is designed to enhance consumer trust in devices and security of technological devices.

IoT devices were also not built with privacy in mind (Maras 2015). A person's privacy can be violated because the data collected, stored, collated, and shared by IoT devices can reveal personal information (or data) about the users of these devices. Depending on the device, this

can include (but is not limited to) a person's movements, habits, routines, hobbies, personal preferences, physical activities, eating habits, sleeping patterns, and even medical information. Users of IoT devices often have little, if any, control and choice over the data that is obtained, aggregated, analyzed, and shared about them and knowledge of the quantity and types of data that is shared about them. To date, IoT devices are not predominately created with privacy-enhancing features built into the architecture of these devices to minimize the collection of data by these devices from the outset (a form of *privacy by architecture*). Instead, what is observed is *privacy by policy*, whereby privacy-enhancing applications are considered post-design to manage the data already collected, stored, and potentially shared by these devices (e.g., notices of data management practices and data management user interfaces). In the European Union, the General Data Protection Regulation (GDPR) of 2018 (EU Regulation 2016/679) also does not impose any obligations on IoT manufacturers to implement technological data protection measures. While the United States similarly does not have a federal law mandating data protection measures by IoT manufacturers, state law does exist. A case in point is the California Consumer Privacy Act (CCPA) of 2018 (Senate Bill No. 1121), which provides California residents with rights over the collection and use of their personal data (Schwartz et al. 2018). As of 2020, laws, such as the CCPA, are the exception in the United States, not the norm.

Conclusion

Everyday objects are increasingly being connected to the Internet in order to collect, store, collate, analyze, and share substantial quantities of data about IoT devices, users of the devices, and the environments within which these devices operate, as well as to facilitate the monitoring of people, animals, plants, and/or objects (which one or ones are monitored depends on the IoT device). IoT devices raise security and privacy concerns that have not yet been adequately addressed.

Emergency · Information · Decision-making · Questioning · Rapport

Definition

Interviewing adults refers to the use of research-based methods for obtaining reliable information needed for critical decision-making during the course of an emergency.

Introduction

The key to ensuring successful outcomes within the emergency services, be it a fire, trauma, or criminal in nature, is in part reliant on gaining reliable information (Nunan et al. 2016). Reliable information may in turn aid effective, critical decision-making throughout an emergency (Alison et al. 2015). However, obtaining such information is a complex task, especially at the front line where the event is often surrounded by chaos and confusion and where there are limited fast-time resources (Dalton et al. 2018). Thus, the information-gathering task is confounded by numerous factors, but in the current entry, we will focus on three key areas of research: (i) the source of the information (i.e., is it a witness, victim, or emergency services personnel themselves?); (ii) the types of questions used to gather the information (i.e., open questions or leading questions); and (iii) the manner in which the questions are asked (i.e., has rapport been developed?). The enormity of this task in these dynamic circumstances should not be underestimated. It is essential that researchers explore the nature in which this information is gathered to help devise workable recommendations and techniques that aid the blue light services to work efficiently and effectively. By utilizing the knowledge underpinning the psychology of communication and the fallibility of memory, well-researched concepts in the psychological literature can help us advise on the best means of gathering full and reliable information and develop tools to assist in this process. Fortunately, with the ever-increasing demand for research development in the domain of blue light services, academic-practitioner collaboration is becoming more commonplace. There is a history of sharing knowledge in respect to information-gathering and decision-making with practitioners across a range of domains (e.g., Alison et al. 2015; Cohen-Hatton et al. 2015). However, we must not be complacent; there is still scope for learning and development.

This entry is structured around the different emergency services themselves, starting with (i) the police, examining frontline communication, and dealing with critical incidents. The entry then examines the limited amount of work concerning (ii) paramedics. Communication and information-gathering are used within this type of organization for different reasons to the police (i.e., potential medical intervention). Finally, (iii) the Fire and Rescue Service, whereby good communication in this domain provides crews with the necessary information to ensure operational competence and effective risk assessment and maximize crew, witness, and victim safety, is described.

Police: Frontline Communication and Critical Incidents

Following an initial call to the emergency services (see Dalton and Milne in press, for more in this area), frontline police officers will often attend a scene to establish (i) initial response requirements, (ii) what has happened, and (iii) who is likely responsible (Milne and Bull 2006, 2016). Thus, it is important that police officers are able to interview witnesses and victims about what they can remember. However, this poses challenges because extracting reliable information from memory at the scene of an incident can lead to both encoding errors (e.g., witnesses reporting details they did not experience) and retrieval errors (e.g., police officers asking inappropriate questions that lead to inaccurate information; Snook et al. 2012). The latter is a great risk for frontline police officers who typically have the least amount of training and experience (Dando et al. 2009). These challenges are extenuated given that frontline officers are often in resolution mode, dealing with dynamic events (e.g., separating a couple involved in a domestic) as opposed to an investigative mode (e.g., gathering information from those involved). The situation requires officers to be in both resolution and investigative mode, a cognitively demanding task (Dalton et al. 2018). There is limited field research looking

at police interviewing at the scene of the investigation. The few field studies that have been conducted have found shortcomings in the way in which police officers interview witnesses, including the overreliance on asking closed questions (Myklebust and Alison 2000) and using leading questions (Wright and Alison 2004). Police officers themselves have reported feeling inadequately trained, ill-equipped, and under pressure when conducting such interviews (Dando et al. 2009).

Due to government cuts and the need for police forces to modernize, the use of technology by the police has increased significantly (Jennings et al. 2014). From police dashcams to the issuing of personal body-worn video cameras, the police are now more accountable for their actions. Body-worn video cameras are attached to the uniform of frontline officers, and, when turned on, these provide a reliable record of all interactions that take place at the scene (e.g., with witnesses, victims, suspects, and/or emergency services personnel themselves). As a result, the recording of such interactions offers a unique insight for researchers into what occurs at the scene of an incident. More specifically, and for the first time, academics and practitioners are now able to obtain an accurate representation of the communication used including the questions frontline police officers ask when in attendance at an incident. To date, research suggests that frontline officers often fail to deploy strategies to build rapid rapport with witnesses and tend to use inappropriate questions (e.g., leading) to gather information (Dalton et al. 2018; Gabbert et al. 2016).

To examine frontline communication, Dalton et al. (2018) were granted privileged access to body-worn video footage over 15 months. This piece of research examined how frontline police officers interviewed witnesses and victims at the scene of an incident. The main objective was to explore how frontline police officers elicited person descriptions about the suspect(s). The research further investigated the impact of contributing factors (e.g., witness intoxication, stress, and vulnerability) on attaining these descriptions. Finally, the practicalities of using body-worn video were documented, such as the quality of the audio and lighting and camera angle. It was found that person descriptions were being elicited using inappropriate questions and that this had the potential to produce vague or incorrect descriptions. However, when appropriate questions were used, witnesses provided a significantly higher number of descriptors. Thus, asking the right questions is key. Decisions are only as good as the information that is fed into making them. That information is only as good as the questions asked. Poor questioning can lead to poor information that can lead to poor decision-making.

The collaboration between academics and practitioners in this area of the emergency services has been fruitful, and a number of tools have been developed. This includes research-based tools and techniques for eliciting information from cooperative adult interviewees. In incidents where there are mass witnesses (e.g., a terror attack; see next subsection), two of the main issues are a lack of time and resources. The Self-Administered Interview (SAI; Gabbert et al. 2009) is a paper-based interview that can be given out at the scene of the incident and is a protocol of instruction and questions that is designed to elicit a written free-recall statement. Studies using the SAI have reported a significant increase in the completeness and accuracy of information (Gabbert et al. 2009; Krix et al. 2016). Moreover, the SAI protects the memory from potentially distorting post-event information (Gabbert et al. 2009, 2012; Hope et al. 2014).

If face-to-face interviews are required, then frontline officers need to be asking the right questions. Working with practitioners, Gabbert et al. (2016) developed an evidence-based Structured Interview Protocol (SIP) and related training, for use by frontline police officers. SIP is based on the premise that the best information is that gathered by open-ended questions (e.g., Tell me what happened), followed by specific-closed questions (e.g., When was that?). The SIP package promotes high-quality interview performance, reduces memory contamination, and has led to increased use of rapid rapport techniques, enhanced "engage and explain" skills, and an increase in appropriate question types, used in a structured manner. Another technique that enhances memory

retrieval during frontline communication is the use of a sketch plan. Sketch plans have been shown to be useful in helping witnesses to explain what they experienced and the location of people and objects (Dando et al. 2009). Research has also shown that sketches can be used with a variety of witnesses, including those who are deemed vulnerable (Mattison et al. 2018).

Terrorism has also added challenges to how police communicate at the front line, especially where mass witnesses are involved. Experiencing trauma is a major concern in all critical incidents (Smith and Milne 2018). In such situations, casualty/witness interviewing is complex because of the confusion and chaos surrounding the event, limited fast-time resources, and the scale of the problem. In addition, gaining reliable information from witnesses to inform the emergency services while taking heed of their trauma is a difficult task and can be compromised by poor interviewing or greatly enhanced with good sensitive interviewing (Smith and Milne 2018). Getting the investigation into terrorism wrong, however, has far-reaching costs to society, not only psychologically but also economically. For example, in one report it has been estimated that one million fewer people visited Paris following the terror attacks, a cost of £644 million (Harris 2016). Getting it right is crucial in ensuring a safe and resilient society.

To ensure best practice, academics and police have worked together examining the challenges involved in managing such critical incidents. For example, Smith and Milne (2018) developed a framework for triaging mass witnesses based on their own experience of dealing with such an incident and a dialogue with police interview advisers involved in developing strategies for this type of investigation. Witness Interview Strategies for Critical Incidents (WISCI) sets out to describe the various considerations needed to develop a witness interview strategy for a critical incident involving multiple witnesses, a triage system. The number of witnesses to some high-profile critical incidents is such that it is usually necessary to put an organizational structure in place to facilitate their management (Smith and Milne 2018). It is only by the development of such an organizational structure that the investigation team can have any hope of managing a large volume of witnesses. Witness interview strategies for high-profile critical incidents use the same framework that is used by witness interview strategies more generally (see Smith and Milne 2018). This framework consists of the following: (i) initial contact, (ii) investigative interviews, and (iii) post-interview process and product. Of particular importance is the fact that critical incidents are characterized by trauma. Thus, understanding how to manage trauma is essential for interviewers. Interviewers must be "open, flexible, and able to adapt to the state and expressions of the interviewee" to achieve rapport and allow them to feel in control of the information flow (Risan et al. 2016, p. 414). Such a skill hinges on the ability to manage emotions. The ability to manage emotions is central to the concept of emotional intelligence which involves "the ability to recognise, appraise and understand emotions on the basis of verbal and non-verbal expressions, to use emotions to enhance one's thinking through reasoning or problem-solving, and to manage emotional responses" (Risan et al. 2016, p. 415). WISCI is a good example of how practitioners and academics can work together to develop a realizable working framework in response to a real-world problem. Another emergency service organization always in attendance at critical incidents is paramedics. It is to this group that we now turn.

Paramedics: Multiagency Working

There is limited work looking at the frontline communication of paramedics. As can be seen from the prior discussion, in the course of a major incident, the collection and dissemination of relevant and reliable information are crucial to an effective and efficient multiagency response (Allen et al. 2014). The techniques used to elicit and share information are, therefore, key to the success of working in harmony (Waring et al. 2017). However, similar to the police (outlined above), a number of factors may impact upon this process within this service, such as (i) the sources of the information and (ii) the communication methods used to gather the information (e.g., open, closed, or leading questions).

Simulation exercises are a method used to help emergency services hone their skills. Training in a realistic simulated environment provides a safe place to gain experience and develop skillsets ready for real incidents (Alison and Crego 2012; Rouse 1991). Exercise Unified Response (EUR), Europe's largest major incident training exercise to date, provided a rich environment for the emergency services to test their multiagency response (London Fire Brigade 2017). The simulation, which lasted 4 days, consisted of a collapsed building that mirrored London Waterloo Underground Station. This project involved all the emergency services as well as members of the public who acted as casualties. This exercise demanded a timely and effective short-term response from the emergency services together with an efficient long-term plan of action.

Body-worn video cameras were used in partnership with London Ambulance Service (LAS), to examine frontline communication (both within and across LAS teams) and the emergency response (Nunan et al. in press). The research focused on day 1 of EUR to capture the initial frontline communication and decision-making in response to the major incident. The project aimed to (i) produce timelines of key stages of LAS's emergency response to highlight successes and challenges faced during the golden hour and the actions of specialist teams, such the Hazardous Area Response Team (HART) throughout day 1 (see Nunan et al. (2016) described later – for similar methodology with the fire service), and (ii) examine LAS's use of multiagency communication and information sharing. LAS's main priority is the preservation of life. Furthermore, the psychological and physical well-being of the casualty may inhibit the collection of crucial information due to the possible onset of trauma and the unconscious state of some casualties.

Nonetheless, the information collected is only as reliable as the techniques used to elicit that said information. Importantly it was found that the importance of successful multiagency working could not be overstated. Underpinning successful multiagency working is the use of effective communication (Waring et al. 2017), which is implemented through information sharing (Allen et al. 2014), joint risk assessments, and timely command meetings. It was also recommended that multiagency talk groups should be utilized more frequently and used to complete a joint risk assessment. In addition, it was outlined that training in areas such as communication skills and detailed briefings should enhance the frontline response.

Nunan et al. (in press) also demonstrated that body-worn cameras can be used as an effective service evaluation tool to examine real-world practices. Body-worn cameras are able to timestamp and capture both live time communication and behaviors during training exercises, which could be revisited and shown as training material or subjected to research analysis (Nunan et al. in press). Body-worn cameras can promote best practice, identify training needs, and highlight areas for future evaluation. The next emergency service to be examined is the Fire and Rescue Service. Are appropriate communication strategies pivotal to this line of business too?

Fire and Rescue Service: Control Room Communication

Information is also the lifeblood of the Fire and Rescue Services, as it provides operational (and nonoperational) crews with the necessary information to ensure operational competence and effective risk assessment, maximizing crew, witness, and victim safety (e.g., Cohen-Hatton et al. 2015). For example, information pertaining to the location of an incident, establishing the type of incident, and identifying potential casualties and risks are elicited in the control and command center during an emergency response call. However, despite regular developments in control and command (e.g., Fennell 1988; London Fire Brigade 2017; National Operational Guidance Programme 2019), attaining incident-relevant information remains a difficult task.

Operational crews in the control and command center (i.e., control room officers) collect a vast quantity of information, and as with similar blue light services, the use of appropriate question types (e.g., open, specific-closed, etc.) impacts upon the quality of the information gained

(Leeney and Mueller-Johnson 2012). Additionally, it is the responsibility of the control room officer to carefully choreograph the movements of each operational appliance and subsequent crew while simultaneously imparting safety advice to those in jeopardy and gathering critical information from witnesses and victims (National Operational Guidance Programme 2019). The multifaceted role of the control room officer, therefore, is often challenging, diverse, and complex and requires an aptitude to effectively and efficiently make decisions based on the information they have gathered. However, gathering reliable information and undertaking effective decision-making that preserves life, prevents injury, and minimizes property damage are cognitively, emotionally, and physically difficult (e.g., van den Heuvel et al. 2013).

Our natural ability to communicate is not conducive to the scenarios faced by control room officers (or any frontline communicator). Control room officers are often faced with high-stake situations, requiring responsive action in short time frames and dealing with people who are often in heightened emotive situations – all factors which do not often occur in everyday communication interactions (Cohen-Hatton et al. 2015). Furthermore, everyday communication incorporates question types (e.g., leading), which are inappropriate for Fire and Rescue Services, indeed, for any emergency services in an operational role. This is because everyday communication is not aimed at gathering reliable information at speed. To the contrary, everyday language includes questions which are often time-consuming and do not translate to information-gathering tasks during high-stake situations (e.g., Leeney and Mueller-Johnson 2012). Therefore, using the right question types to gather accurate information is a skill that must be learned and nurtured if the Fire and Rescue Service (or indeed any service) is to further develop their control and operational crew communication.

Research conducted via body-worn cameras attached to London Fire Brigade frontline responders during EUR (as explained above) examined frontline communication and the handover of information over time (Nunan et al. 2016). This project offered an insight into the communication strategies employed in fire and rescue personnel frontline communication and demonstrated what happens when a part of the communication chain is broken. A breakdown in frontline communication adversely affects the reliability of the information collected, the sharing of such information, and the quality of subsequent decisions. It is evident, therefore, that training is required in areas such as communication skills, effective questioning of civilians, and detailed briefings (Nunan et al. 2016). Furthermore, this project demonstrated the effectiveness of evidence-based tools (e.g., body-worn video), to observe frontline communication, with the purpose of supporting, developing, and enhancing frontline communication and response (Nunan et al. 2016).

In response to those initial findings (Nunan et al. 2016), and in collaboration with Fire and Rescue Services across the United Kingdom, research has assessed communication in the control and command center (Shawyer et al. in preparation). With privileged access to control and command emergency recordings, alongside a survey to establish perceptions and understanding of questioning techniques, rapport building techniques, and barriers to communication, the present research focused on working toward the development of a bespoke communication protocol. Initial findings from the first phase of this research have suggested that a number of barriers to optimum communication exist: a combination of individual and situational factors. For example, a stressed and confused caller, with a patchy mobile phone signal, trying to adapt to the control officer's agenda (e.g., the location of the incident, alongside the nature of the incident) and questioning, can all hamper attempts to gather reliable and incident-relevant information in a timely manner. An examination of the emergency recordings also revealed communication in the control and command center may not always have been wholly effective; that is, the communication strategies used to elicit information sometimes relied on the use of ineffective question types (e.g., leading, closed, forced choice questions), similar to that found in previous research (e.g., Leeney and Mueller-Johnson 2012). This project has demonstrated a need for additional

support, development, and enhancement in communication techniques in control and command center staff. It also provides initial insight into the potential barriers which can impact of the effectiveness of control and command communication and decision-making.

Conclusion

This entry has explored how the emergency services communicate at the front line. While each service is responsible for gathering different types of information pertinent to them, it is clear that all face similar challenges. For example, research across the emergency services has highlighted the need to ask the right questions, in the right manner. Thus, asking open-ended questions and developing rapport are key to gathering reliable information. The entry has also identified a number of tools that have been designed in partnership between academics and practitioners to aid and improve information-gathering by the emergency services. Finally, the use of technology and specifically body-worn cameras can be "an effective research tool to examine front-line communication, promote best practice, highlight areas for future training needs, and further research areas" (Nunan et al. 2016, p. 52).

Definition

Interview: A deliberate, structured, interaction in which one individual attempts to obtain needed information from another individual.

Introduction

There are various situations (e.g., disasters, crimes, accidents) in which a first responder's action is urgent and may depend on information only available from a child. This entry is designed to help responders effectively get the information they need from children when it is needed immediately, as well as when the time frame can be extended. As discussed in this article, a productive interview must be tailored to the developmental level of the child. Although individuals beyond late childhood or early adolescence may generally respond to interviewing techniques used with adults, different techniques are required with child interviewees. Further, toddlers, preschoolers, and elementary school students present varying challenges as interviewees and hence require different approaches. But in all circumstances, effective interactions with children require special efforts to minimize their anxiety and gain their trust and cooperation. This process is heavily influenced by the interviewer's approach to the child when they first meet; thus knowing the strategies presented in this chapter in advance contributes significantly to the outcome of the interaction.

This article begins with a review of best practices for the vitally important step of establishing rapport with children of different ages. Next, the discussion advises first responders on how to establish the purpose of the interview for children at different developmental levels. Then, expectations for the provision of information from younger and older children are reviewed. Techniques for obtaining information from interviewees of different ages and in different contexts are then presented, followed by a discussion of considerations when interpreting children's responses.

Establishing Rapport

The first step to a successful interaction with a child of any age is to establish rapport, even when time is of the essence. Good rapport is characterized by comfortable interactions, mutual cooperation, and open communication. Therefore, the primary goal is to help the child develop the trust necessary to provide the needed information. Although more experimental evidence is needed on the contributions of particular components of rapport building, research findings establish that starting an interview by building a good working relationship increases both children's accuracy and completeness in response to subsequent questions (e.g., Price et al. 2016). In short, rapport building should not be skipped, even when limited time is available.

There are several quick and effective adjustments to facilitate rapport (see Teoh and Lamb 2010). For instance, if the child is small, the adult should get down on the child's eye level. The interviewer should convey friendliness through open posture and a warm voice. Toddlers and preschoolers may need to be near an attachment figure (parent or other loved one) or to hold an attachment object (favorite toy or blanket) to feel safe and secure. Toddlers often fear strangers, so the interviewer should not initiate touch but rather give the child as much control as is possible. Crying children do not benefit from criticism or invalidation of their feelings. A better response to crying is a sincere "I know why you are upset and I'm here to help." Additionally, when children get loud, using a calm, soft voice may entice them to stop yelling or crying so they can hear what is being said to them. The physical comfort of the child also needs to be attended to. Toddlers and young preschoolers lack an awareness that adults do not know everything that they know, so these young children may mistakenly assume that adults are aware of their physical injuries and fail to point them out. Lastly, for children of all ages, interviewers should calmly and clearly assure the child that they are there to help and introduce themselves in simple, direct language; "I'm Officer Smith and I will help you."

In situations where more time and resources are available to devote to rapport building, there are several additional techniques that are effective. If possible, the child should be given a choice of who they would like to talk to. Some children connect better with people who look like them, are of a specific gender, or remind them of a trusted adult. For children of preschool and elementary ages, adults should start with a warm-up conversation about a non-threatening topic such as a recent event (holiday celebration, birthday party, family gathering) or hobby (sports, music, school topics). Results are best when adults pose invitations for an open-ended response (i.e., "Tell me all about your last birthday") rather than directive questions that dictate a specific kind of response (i.e., "Where was your last birthday party?") (Price et al. 2016). Adults should keep in mind that younger children's attention spans are much shorter than older children's, and thus the length of these warm-up conversations should be brief. Furthermore, responders should keep the continual physical comfort of the child in mind as the interactions proceed. Young children need to be explicitly told that they can take a break and they should not be expected to sit still for long periods of time. As long as the child is engaged in the interview, the responder should tolerate fidgeting, walking around, playing with toys, etc. Responders can redirect the child's attention as needed using simple and direct statements, e.g., "I cannot hear you when you are under the table. Please sit in the chair. We need to do more talking."

Conveying Purpose

After rapport has been established, the interviewer needs to clearly convey their purpose for talking with the child and the child's role as an informant, practices which appear to help children be more informative (Teoh and Lamb 2010). A word of caution here: *Interviewers should limit their questions to only topics that are essential for them to do their current job. If the purpose of the questions is to gather evidence for criminal or civil court and is not urgent (*i.e., *sexual abuse victim, custodial investigation), STOP!* Poor questioning techniques can contaminate a child's memory, making their future testimony suspect. However, well-trained child forensic investigators can elicit valuable information from children. Evidence shows that it takes many hours of intensive training with detailed feedback on techniques to master standard child interview protocols (Lamb 2016). In short, if the information needed from a child will have serious legal consequences, call in a trained child forensic psychologist as soon as possible.

When time is urgent, a clear, simple statement of the emergency responder's purpose will suffice. For instance, "I need to make sure everyone is out of the building" or "I will help you find the grown-ups you came with." Responders should use "I" language and address only the immediate purpose.

In situations where the responder is not rushed, the responder may need to reassure the child that the child is not in trouble. Preschoolers and young elementary children will benefit from an invitation to share in the responder's purpose: "You can be a helper." Due to preschoolers' egocentrism, they need to be explicitly told that they know more than the interviewer and that it is ok to tell the responder if the responder is wrong. Preschoolers and elementary-aged children should be clearly instructed about the "interview rules." That is, children should be told to tell the truth, say "I don't know" rather than making up an answer, and to correct the interviewer if they make a mistake. Then, children can be given practice using the rules. The interviewer could say, "What did you have for breakfast? What did I have for breakfast?" Ensure that children respond that they do not know what the interviewer had for breakfast.

Understanding Age-Related Changes

The information children can provide depends both on age and the types of questions directed toward them. Although infants can recognize information – e.g., can hear a voice and know that it is familiar – the capacity to remember and

report personal experiences typically emerges in the toddler years. It was once assumed that children could not remember their experiences until they were about 4. It is the case that adults have difficulty retrieving memories for events that occurred before this age, a phenomenon described as childhood amnesia. However, it is now well established that many 2-year-olds can provide accurate responses to specific questions about their recent past experiences (Fivush 2011).

Clear developmental improvements are apparent in underlying memory capacities. Three-year-olds often can provide some information about past events in response to general questions (e.g., "Tell me about the accident"), although the amount of information they provide is still limited and does not typically include a great deal of detail. Older preschoolers and kindergarteners provide more extensive reports of their experiences in response to general, open-ended questions and with age, provide increasingly complete accounts, including descriptive details. By about age 7, young interviewees rely much less on the interviewer's specific questions and can provide rich, independent narrative accounts of some types of events. By the end of the elementary school years, most children have the memory capability to report events in an adult-like manner, often including information about time and place, the chronology of the event, and even some detail about emotions and thoughts (Reese et al. 2011).

Memory depends on a variety of influences in addition to age. Children's reports may exceed expectations for their age level when they have a great deal of knowledge regarding an event (see Baker-Ward et al. 2009). In this case, they may take in more information about an experience and retain it over longer intervals than is the case when they are asked to report events they do not fully understand. For example, a child who is an avid baseball fan will likely report a variety of actions and details ("It was during the third inning when the team's pinch hitter took bat") than a less enthusiastic peer can recall ("Sometime after the game started. . .").

The nature of the to-be-remembered event also impacts the child's subsequent report of that event. The anxiety experienced by the interviewee as an event transpires is of particular relevance to first responders. The existing evidence, however, does not support straightforward conclusions about the relationship between stress as an event is experienced and subsequent memory for the experience. It appears that stress affects what the individual focuses on during the event, a process that is affected by a child's developmental level and other factors (Quas et al. 2014). Of course, if actions or descriptions are not taken into memory, they cannot be reported. Notably, the "weapon focus effect" involves an individual's focus on sources of danger, limiting the attention they can direct to other aspects of the experience (Fawcett et al. 2016). Thus, responders should accept that a child may not have available in memory some apparently obvious information about an anxiety-provoking event. This limitation notwithstanding, it is clear that children can provide a great deal of information about stressful experiences and that supportive interviewing reduces suggestibility (Quas et al. 2014).

Regardless of the age of the individual and the type of event, memory is subject to change over time. In addition to loss of information as time goes by, the content of memory can be altered by experiences that transpire after the initial occurrence of the event. Memory is sometimes erroneously presented as functioning as a video recorder, resulting in an exact copy of an event. However, in actuality, memory is a dynamic process, with events often reconstructed as knowledge changes (Baker-Ward et al. 2009). It should be emphasized that such constructive processing is different from intentional lying in that individuals are reporting events as they understand them. For instance, when adults omit very salient details from an initial event report and include them only later, the inconsistency in their reports may indicate lying. In contrast, a child's provision of additional detail over time often simply reflects growth in the understanding of what listeners may want to know. Similarly, a child who initially describes a car as "a race car" may later report that it was a "BMW." Furthermore, toddlers and preschoolers tend to report information in a piecemeal fashion, sometimes adding important new details even after they indicate "that's all I can remember."

Children, especially those younger than early elementary school age, may even remember new details at a later interview. This inconsistency is developmentally normal and generally doesn't contradict information initially reported but rather augments it. So while an adult's omission of the fact that the man he saw was over 7 ft tall would be suspect, a child's provision of the fact that the man was "really, really tall" a few days later would not be unusual among preschoolers (Brubacher et al. 2019).

Obtaining Information from Children

In talking with children, an effective interviewer provides just enough guidance and direction to enable a child to participate fully in the exchange of information. The adult's contributions, in effect, compensate for the child's developmental limitations. This approach is an example of the technique psychologists describe as scaffolding. In the interview context, the responder scaffolds the child's involvement by providing structure and insuring that the child understands the interviewer's questions. In doing so, the interviewer bridges the gap between the child's level of cognitive and language development and the skills needed to effectively convey extensive and accurate information. Consequently, the child's interview performance exceeds the level of competence the child could demonstrate without such scaffolding. Further, the child's current skills determine the amount of appropriate scaffolding that is required, and generally younger children need more guidance than older children. Note that the interviewer is supporting the child's own contributions to the interview, rather than fully controlling the interaction.

Effective interviewers must accommodate the child's level of language development. The child's acquisition of language involves more than simply growth in vocabulary. Toddlers and preschoolers are especially likely to overextend the meaning of words to cover whole categories and to incorporate related objects. For instance, "yesterday" often means "any time in the past" to toddlers. Furthermore, a younger preschooler may call a zebra a horse or a teenager a man.

Similarly, younger children may also limit a category much more severely than would be the case with adults. A child carrying a stuffed animal may report that he didn't have a toy with him, because the stuffed animal is his "lovey," which he sees as its own category. Interviewers must also keep in mind age-related changes in the child's capacity to understand grammatical structures and conventions of conversations (as discussed below).

In general, in situations in which the need for information is not urgent, hierarchically structured interviews result in the most complete and accurate account of the child's experience. Hierarchically structured interviews move from the most general prompts to increasingly specific requests for information to obtain the child's complete account of the event.

In some circumstances, the responders need immediate information in order to take emergency action ("Who is in the house right now?"). In such situations, applying the full hierarchical interview structure would require time that isn't available. In these cases, the emergency responder should skip the open-ended section and instead immediately present wh-questions to obtain the needed information as quickly as possible. In most cases, beginning with more focused questions is also appropriate for working with young toddlers.

Open-Ended Prompts. Following the establishment of rapport and a child-friendly discussion of the purpose of the interview, the hierarchical interview begins with open-ended prompts, which are general questions and statements by an interviewer that do not direct the respondents' attention to a specific component of an experience.

For example, "Tell me what happened when Mommy got hurt." As needed, the interviewer follows up with non-specific probes to obtain additional information, e.g., "Tell me more about that," or "What else do you remember?" This practice avoids introducing incorrect information that could contaminate a child's later report and, indeed in some instances, the child's memory for the event.

To support the child's continued engagement in the interview, the respondent should provide

ongoing, positive feedback by simply acknowledging the child's response. For example, the interviewer may say, "uh huh," or "ok." These simple reactions indicate to children that it is their turn to talk. Although the child may require praise to continue talking, interviewers must be very careful to avoid reinforcing a particular answer or response. To maintain the child's engagement without the risk of altering a report, it is best to use phrases like "You're doing a good job," or "Thank you for talking with me." It is important to avoid linking praise and specific answers because young children typically want to please adults. Thus, they may alter their reports to provide information that they assume will elicit praise. Because children often see adults as authority figures, they are sensitive to the interviewer's reactions to their answers.

Focused Prompts. Once the child is no longer providing new information in response to open-ended prompts, the responder may move on to the next phase of the hierarchical interview by presenting focused prompts. These more targeted requests for information are questions and statements by an interviewer that direct the respondent's attention to a specific component of an experience. These include the use of who, what, when, and where questions as well as yes/no questions.

The interviewer should craft wh-prompts using details a child has already provided; e.g., "You said the car didn't start. Where was the car when it didn't start?" Questions asking who, what, when, or where tend to elicit more useful information than yes/no probes (Stolzenberg and Lyon 2017). Such wh-prompts target a particular fact without feeding the child the answer, as is the case with yes/no questions. Further, wh-questions generally avoid providing the child with information that could be incorporated into subsequent reports of the event, risking contamination of the child's memory.

Effective wh-prompts, however, require careful phrasing. Children younger than about 7–8 have difficulty with how and why questions, which should be avoided. Responding to these questions typically requires an understanding of causal relations and inferring others' perspectives and motivations, which are usually beyond the cognitive capabilities of young children (Malloy et al. 2017). Similarly, younger children have difficulty with abstract concepts such as clock and calendar time. It is always advisable to scaffold children's reporting of the time of the event by linking it to regular occurrences in the child's day (e.g., "Was that before your mom got home from work?") or landmark events ("Was that after you started kindergarten?"). In addition, the interviewer should remain aware of differences in children's and adults' understanding of the world, in order to avoid limiting the child's responses. For instance, in response to an interviewer's question about what a child had for lunch, a 3-year-old reported that his babysitter did not give him lunch. Follow-up questioning determined that the child's caregiver had given him eggs for lunch, which he did not consider to be lunch because "eggs are for breakfast." Any questions about his babysitter's care were alleviated when the child was asked to tell the interviewer everything he had to eat at the caregiver's house. This example also illustrates the importance of follow-up questions to maximize the information that can be reported in response to the prompt.

If a child does not know the information that a responder needs, a little creativity may help. For instance, a toddler may answer "What is your mom's name?" with "Mommy" but may provide her name in response to "What does your Grandma call your Mommy?." Similarly, if a young child cannot tell their address or phone number, they may be able to name their school or daycare, and a call to such facilities may yield the information.

In addition to the importance of phrasing questions that are sensitive to the child's understanding of the meaning of words and knowledge of the world, interviewers should also be aware of developmental limitations in interpreting word order. All interviewees, especially children, will benefit from short, direct questions. Such questions require less working memory and minimize the steps required to comprehend the interviewer's request. Table 1 below lists several specific recommendations for presenting appropriate questions to child interviewees. As indicated in the

Interviewing Children, Table 1 Practices for interviewing children

Dos	Don'ts
Start the interview with open-ended prompts Example: "Tell me what happened."	Immediately jump to specific wh- or yes/no questions when there is time to obtain a child's full report Examples: "Who started the fire?" "Did your Mom start the fire?"
Use who, what, when, and where questions Example: "What happened when your Mom drove off the road?"	Use questions that ask about how or why Example: "Why did your Mom drive off the road?"
Use follow-up questions to understand the meaning of a child's statements Example: *Child:* "Emma is still in the burning house!" *Interviewer:* "Who is Emma?" *Child:* "My goldfish."	Make assumptions about a child's intent or understanding Example: *Child:* "Emma is in the burning house!" *Interviewer assumes Emma is a person.*
Use questions that prompt with actions or observational-based cues the child has already provided Example: "What happened after the car slid off the road?"	Use questions that prompt with time-based cues Example: "What happened last night?"
Scaffold a child's report about time Example: "Was that before lunch?"	Use questions about clock or calendar time Example: Was that around 3 pm?
Use the active voice Example: "Where did the man hide?"	Use passive voice Example: "Where was the man hiding?"
Ask one question at a time Example: "Who was there?"	Use multipart questions Example: "Who was there and what did they say?"
Use simple, direct prompts Example: "Tell me who did it."	Use tag questions Example: "You know who did it, don't you?"
Reference actual behaviors or events Example: "Where does your mom usually go?"	Reference hypothetical events Example: "What if I was your Mom...where would I be?"
Instruct children to respond Example: "Tell me about . . ."	Use indirect requests Example: "Do you want to tell me about that?"
Have a child point on their own body or use actual photos of a location Example: "Show me on your body where the man hit you." Example: "Here are some pictures of the park. Show me where the car was parked."	Use toys as props to reenact an event Example: "Show me on this doll where the man hit your Mom." Example: "Point on the map to where you last saw the car."

table, the passive voice, multipart questions, and tag questions should be avoided.

Props. When verbal information from a child is not forthcoming, interviewers are often drawn to the use of dolls or other props (for review, see Poole and Bruck 2012). Although it seems reasonable to offer the option of a nonverbal response in this situation, the practice is problematic, especially for toddlers and preschoolers. These young children have difficulty in seeing a doll both as a representation of the self and as a toy; consequently, dolls are not effective as interview aids for this age group. Because the practice does not elicit reliable information, it should be used only as a last resort and then with the understanding that evidence obtained in this manner is generally suspect. Similar concerns apply to the use of body diagrams. It is also intuitively appealing to allow children with limited verbal skills to act out the events under discussion, using a variety of props. Although young children may generate some additional information using props, they also become distracted by the situation and play with interview aids in a manner that results in false evidence. Further, research shows that older children do not generate additional evidence with dolls and props. So, younger children don't benefit from such interview aids, while older children don't need them.

Although toys are not effective interview aids, more realistic objects may be useful in obtaining information from younger children in some circumstances. They may be able to indicate on their own bodies (cf. on doll) where an injury occurred. Similarly, when information about a location is necessary and is not reported verbally after sensitive questioning, the use of an accurate photograph (in contrasts to a map) in the investigative phase may assist the child in identifying a location. Nonetheless, such techniques should be used only when attempts to obtain the information verbally have not proven successful.

Interpreting Children's Responses

The best rule of thumb for interpreting young children's response is to assume they are telling the truth but to remember that children's truth reflects their perceptions of the world. Concocting a believable lie involves cognitive skills that exceed the developmental capabilities of toddlers and young preschoolers. Lying – that is, constructing a false story in order to manipulate someone else's understanding of events – requires a number of abilities that are not generally well established until the early elementary school years. These capabilities involve the complicated understanding of how minds work, including knowing that thoughts are private and can differ among people; taking the perspective of another person; and attributing motives and intentions to others. It is certainly the case that young children may falsely deny actions in response to yes/no questions or direct probes. For example, a 4-year-old child whose face is covered with sprinkles and powdered sugar may say "No!" when asked "Did you eat my doughnut?" or say "It was the dog!" in response to "Who ate the doughnut?". These simplistic false reports, provided in order to avoid punishment, differ from a spontaneous narrative about an event. It would be a rare preschooler who would provide a detailed description of the dog's eating the doughnut without being asked specific questions about the missing pastry (for review, see Talwar and Crossman 2012).

To argue that young children do not concoct sophisticated lies as part of a scheme does not imply that all their statements would correspond to an adults' version of what happened. Especially given their limitations in understanding cause and effect and intent, a child may provide a report that does not reflect what actually transpired. For example, a 3-year-old boy asked to describe what happened during a visit to the doctor said that "The nurse put blood in my finger!" in attempting to report the nurse's obtaining a drop of blood to check his hemoglobin. Such limitations are especially relevant in situations in which the task involves differentiating intentional and accidental injuries. To illustrate with a mundane experience, a preschooler who reports that "Mommy hurt me!" may reference a situation in which the mother unintentionally clipped the child's nail too closely. Thus, it is important for an interviewer to be mindful of assumptions made from an adult's worldview. It is very important to clarify children's meanings with carefully selected follow-up questions, as discussed above.

Of course, not even the most carefully constructed follow-up questions can resolve all ambiguity. Identifying the source of information in memory is challenging for children as well as adults. Most children have difficulty, for example, in remembering whether their teacher or their neighbor told them about an upcoming event, although they may report in detail what they heard in the conversation. Misremembering the source of the information is a common error and in no way indicates that the information itself is inaccurate (Brubacher et al. 2019).

It is also the case that the credibility of a child's report cannot be assessed using the standard applied to adults. As indicated above, children may provide only a few pieces of information spontaneously, may not elaborate their responses, and may give their account in a piecemeal fashion. However, experimental evidence (Gordon and Follmer 1994) indicates children give accurate information in response to open-ended questions even when the information is limited and may introduce salient details later in an interview without contradicting the earlier report.

One final point of emphasis is the importance of documenting the child's report as completely and accurately as possible as soon as time permits, especially if an ongoing investigation is likely. Documenting the child's report involves reporting as much of the interview as possible, including the procedure used to establish rapport, the interviewer's actual questions, the child's verbal and nonverbal responses, and any additional information that could help later interpret the child's account.

Conclusion

Getting useful information from children is not easy. It requires sensitivity, patience, and skill on the part of the responder. But learning and using best interview practices is well worth the effort. With effective scaffolding from adults, even young preschoolers can provide answers that can determine the success of an emergency action or influence the outcome of a forensic proceeding.

Definition

An Intruder Detection System (IDS) is an automated technology designed and implemented to detect and communicate the presence of a person or object in a designated zone. IDS provides the *detection* element in a security system which holistically deters, detects, delays, and responds.

Introduction

Intrusion Detection Systems (IDS) have become a protection norm in both domestic and commercial premises, driven by cost reductions, a user-pay approach to security, and an increased perceived need (Brooks 2014). Such a need is driven in part by burglary risks, a "high-volume crime that impacts upon the well-being of the general public" (Mawby 2007). While no IDS can physically prevent a theft, they do notify of such activity. As a result, IDS have become a common method of protection. Therefore, this entry introduces IDS, its principle and geometry of detection, taxonomies of sensing detectors, and applied levels of protection.

What Is an Intrusion Detection System?

IDS have many different names. ASIS International refers to these systems as *Intrusion Detection Systems* (Walsh and Healy 2012, p. 91), whereas in Australia, they are *Intruder Alarm Systems* (Standards Australia 2007). Other terms to describe IDS include Burglar Alarms, Alarm Systems or simply, Alarms. IDS is also a commonly used term within cybersecurity, being a device or software that monitors a computer network for malicious or policy violations (Abaimov and Martellini 2017, p. 31). Nevertheless, for this entry, IDS is an element of a physical security system designed to detect and communicate the presence, entry, or attempted entry of an unauthorized intrusion activity into a designated zone.

The security literature considers IDS as a dichotomy between domestic and commercial; however, there is little difference in their principles, design, and, to some degree, application. Factors that do define these systems are the diagnosed threats and risks that drive the inferred robustness of the IDS as a treatment strategy to detect threats.

Defense in Depth

The function of IDS is to support the Defense in Depth strategy. Defense in Depth protects people, information, or assets through the elements of *deter*, *detect*, *delay,* and *response* (Garcia 2008, p. 58). In the security system, IDS both *deters* and *detects* a person or object of interest.

Detection of overt or covert movement must be accomplished to prevent loss or harm, achieved through a variety of sensing detectors. Therefore, detection is a critical function of the Defense in Depth strategy, as without detection it is only a matter of time before an intruder penetrates

all barriers (delay) to reach their desired asset. Effective security is related to time after detection; therefore, timely detection is required to facilitate apprehension (Garcia 2008).

Principle of Intrusion Detection

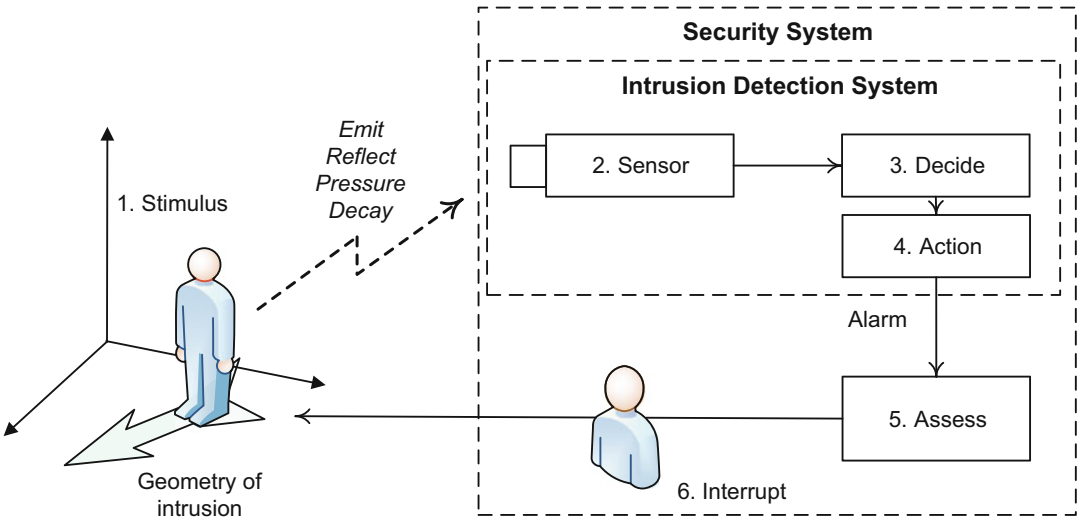
The principle of detection relies on the use of sensing technology to discover and respond to the presence of a person or object within a defined field of view. All automated systems comprise sensing, processing (decide), and output (action) componentry. Figure 1 schematically highlights how an IDS senses the presence or activities of a person or object in response to anomalous activity.

- *Stimulus* (1) is introduced by the presence of a person or object. Stimulus could be emitted energy such as infrared radiation, a reflected wave such as microwave radiation, a pressure wave, or molecular decay.
- The *sensor* (2) reacts to a compatible *stimulus*. There is a wide range of sensing detectors, ranging from a *passive infrared* detector seeking emitted infrared radiation, *break-glass* detector tuned to the frequency of breaking glass to an *active microwave* detector that receives a Doppler shifted wave.
- An algorithm *decides* (3), based on a priori threshold, whether to *act* (4) in producing an alarm which indicates an anomalous stimulus has been detected.
- A person or thing *assesses* (5) the alarm to judge and, if appropriate, initiate a human response to *interrupt* (6) the person or object.

These events demonstrate that the process of intrusion detection is not an instantaneous event, nor a guaranteed outcome.

Geometry of Intrusion Detection

Detect is the discovery, through sensing a stimulus, of a person or object. IDS detection is achieved through the geometry of protection (Underwood 1984), which highlights an intruder can be detected through crossing a line, moving through an open space, or contacting a specific point accordant with an intrusion geometry. The aim of employing sensors across this geometry is to achieve what Garcia (2008) and Wyss (2009) term "balanced protection," where every viable intruder scenario pathway achieves the same level of difficulty. For spatial detection,



Intrusion Detection Systems, Fig. 1 The principle of detection. (Adjusted from Brooks 2014, p. 687)

the stimulus may move into a sensing detector's field of view from many directions, horizontally and/or vertically. Furthermore, the stimulus may move fast or slow, be large or small, be close or far from the detector, or have a different chemical make-up. Such vector movement can be considered the geometry of intrusion, articulated by the designated alarm zone.

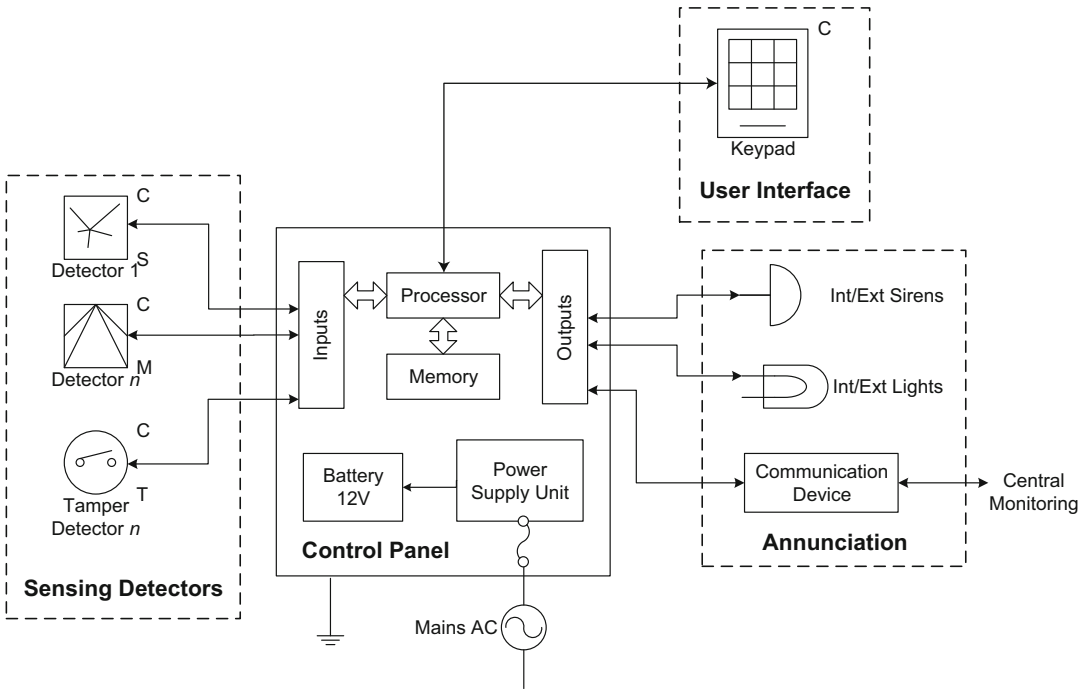
A sensing detector must be designed and applied to maximize its strength based on its underlying physics sensing principle while minimizing its inherent weakness. For example, a passive infrared detector most effectively senses targets moving *across* its field of view at an ideal distance and speed within a temperature threshold.

Sensing detectors can be defeated through a variety of methods, such as bypass, spoofing, or technical defeat. Bypass may include going over, under, or around the detector's field of view. Spoofing is defeating the detector by moving through its field of view without stimulating the sensor above its activation threshold. Technical defeat is the ability to modify the input or output function of the IDS. The ability to successfully defeat a detector requires both capability and knowledge of the detector, the IDS, and its applied environment.

Taxonomy of Sensing Detectors

The sensing detector is often not considered the primary element of the IDS; instead, the focus is the Control Panel (see Fig. 2). Nevertheless, there are different taxonomies in the categorization of detectors. For example, Smith and Brooks suggest that "detection technologies can be categorised as single or many-dimensional" (2013, p. 141) or in accordance to Underwood, by their geometry of protection (1984, p. 137). Nevertheless, taxonomy can best be presented in accordance to detection geometry (Table 1).

In contrast, Garcia's (2008) classification of detectors employs an *application* taxonomy with passive or active, covert or visible, line-of-



Intrusion Detection Systems, Fig. 2 Typical IDS. (Brooks 2014, p. 689, reproduced with permission of Palgrave Macmillan)

Intrusion Detection Systems, Table 1 Geometric taxonomy of sensing detectors

Detection	Geometry	Example
Point	0	Operates at a zero-dimensional point. Examples are door reed switches and micro-switches
Line	1	Operates as a dimensional line. Examples are active infrared photoelectric beams or optic fiber cables along walls or fences
Wall or blanket	2	Operates in the vertical and horizontal dimensions. Examples are vibration detector on walls or active stacked infrared photoelectric beams
Volumetric	3	Operates within a region of dimensional space. Examples are microwave, ultrasonic, and passive infrared detectors
Volumetric and time	4	Operates within a region of dimensional space and time. Examples are surveillance system with a record and replay function

Adjusted from Smith and Brooks 2013, pp. 141–142

Intrusion Detection Systems, Table 2 Applied IDS security

Applied security	Sensing geometry	External alarm	Anti-tamper	Communication line monitor	Central monitor
Low threat	Single point	No	No	No	No
⇕	Volumetric	Maybe	Yes	2-state	Maybe
⇕	Multipoint	Yes	Yes	3-state, including unarmed	Yes
High threat	Multipoint and overlapping fields	Yes	Yes	4-state, with fault and tamper	Yes
	Multipoint, overlapping, and hierarchical logic	Yes	Yes	Active encryption	Yes

Adjusted from Brooks 2014, p. 690

sight or terrain-following, volumetric or line detection, and application. Finally, detectors can also be categorized by the sensors underlying physics of operation such as radio, microwave, infrared, or x-ray.

Elements of an Intrusion Detection System

A typical IDS is a system that integrates discrete sub-systems or components (Fig. 2). The Control Panel comprises a central processor, memory, input and output interfaces, power supply, and battery back-up. Detectors will comprise of various types of sensors. A User Interface, such as a keypad, allows users to interact with the IDS. Finally, Annunciator may include external and internal audible warning devices and lights and, for an off-site monitored system, some form of external communication.

Levels of Applied Detection

From an application context, as threats and risks increase, so should the capability of the IDS (Table 2). With a lower threat, an IDS may only require point detectors and local alarm annunciation. As threats escalate, the degree of protection should be commensurate to not only the detection but also unauthorized tamper attempts. For example, two detectors that have overlapping fields of views to increase the probability of detection, hierarchical detectors that apply an OR logic, the use of detectors on enclosures (anti-tamper) to sense access, and that communications lines are supervised to mitigate bypass. Tamper resistance

is important as this is the capability of the IDS to withstand an internal covert attack.

Conclusion

Intrusion Detection Systems have become commonplace within our built environment, used as a situational crime prevention strategy to target hardens. Thus, the application of these systems supports the security principle of Defense in Depth through their ability to sense intrusion and initiate a response, increasing the risk to offenders and altering behavior. The ability to detect is achieved through the detector's sensor, which reacts to a defined stimulus such as a person or object within a field of view or detection zone. Nevertheless, the ability of a sensor to achieve efficacy in detection is achieved through the likely geometry of intrusion, as well as the greater security system.

Definition

Reconstruction is the combined process of applying scientific methods, physical evidence, and reasoning, to determine the most probable sequence of events that occurred during an incident or the commission of a crime (ACSR 2019).

Introduction

This entry explores the process of scene reconstruction focusing upon the scientific methods, technologies, and apparatus used when reconstructing small and large-scale incidents. The purpose of reconstruction is to aid investigators in determining what happened and how it occurred through the examination and analysis of preserved incident sites, recorded digitally and/or physically using scientific methods (Chisum and Turvey 2011). Over the last decade, there has been a proliferation of reconstruction technologies and methods (see entry ►"Drones") which have benefitted law enforcement practice worldwide. Not only in the handling of criminal investigations but also in the management and assessment of incidents resulting from acts of war or terrorism as well as accidents and natural disasters.

Generally in the criminal realm, shootings, homicides (Buck et al. 2013), and road-traffic accidents (Buck et al. 2007) have been the primary focus of reconstruction efforts over recent years. This is due to their complexity and the increasing involvement of specialists such as collision engineers in the case of road traffic accidents, or blood pattern analysis (BPA) experts and ballistics specialists in the case of shootings and homicides (Houck et al. 2018). As such, the consultation of these experts and others has also become commonplace when reconstructing substantially larger mass incidents and emergency scenarios, such as plane crashes, explosions, acts of terrorism, and fire investigations. As due to the mechanic nature of these incidents, investigators can determine whether the acts may have been criminal or accidental, such as in the case of plane crashes where the positioning of debris can indicate the site of impact (AAIB 2017). In addition to this, understanding of the mechanism by which the incident occurred may also prove valuable to manufacturers or policy makers to limit the possibility of future occurrence.

With regard to this, unlike many of the other tasks carried out by law enforcement, mass disaster incidents demand heightened multi-agency cooperation to manage the safety of the public and practitioners over potentially large areas, as well as taking care to record, process and package any evidence likely to determine the cause of the event. As such, reconstruction is becoming an increasingly valuable tool, providing investigators with new insights from new perspectives to support more efficient practices. In addition to this, the results of these large-scale reconstructions are also valuable to local government, utility providers, and engineers to facilitate recovery of the area, as well as aiding future law enforcement training to inform procedures and practice worldwide.

However, despite improved capture methods and faster computing sometimes time constraints, cost, staff, and equipment availability mean that not all incidents are mapped completely, with some portions of incidents being prioritized over others. With this in mind, Houck et al. (2018) classify reconstructions into four main categories; item level, single incident level, event level, and large scale.

- *Item Level*, where the reconstruction is of a single object of interest such as a firearm.
- *Single incident level*, where the focus is on a portion of a scene such as a broken window or confined space.
- *Event level*, this includes all parts involved in an act such as an entire homicide scene.
- *Large-scale*, these include physically large incidents more commonly associated to natural disasters, accidents and acts of terrorism.

With considerations to these classifications, multi-method approaches are often used to ensure an acceptable level of accuracy is achieved. Therefore, this next section explores past and present reconstruction techniques, exploring limitations and abilities of each approach, then this entry concludes with the outlining of state-of-the-art techniques.

Reconstruction Techniques

Sketches and Drawing

The role of scene reconstruction in investigations was acknowledged early on in Hans Gross's

(1893) Handbook for Examining Magistrates as a System of Criminology (later translated by Adam and Adam 1962). Although a great deal of time has passed since this publication, scene sketches are still the most common practice for crime scene reconstruction (Gardner 2012). The purpose of a scene sketch is to compliment photographs and notes taken at the scene, as typically photographs are later back located onto sketches (Ruffell et al. 2014). Generally, initial scene sketches are not to scale, however, scale and measurements should be recorded where possible and added to sketches using established recording methods (Houck et al. 2018). Although this method is tried and tested in crime scene reconstructions (Gardner 2012), upscaling this approach to large accident and disaster scenes is challenging due to the scale and complexity of these incidents and the time-consuming nature of the method.

However, in small-scale scenarios where a sketch may be more appropriate, the sketch can be refined and redrawn using Computer Aided Design (CAD) software after the fact providing associated measurements have been recorded (Houck et al. 2018). These Three-dimensional (3D) CAD drawings are a commonplace technique as the investigator can introduce and move scaled objects within the drawing such as people, weapons, or furniture to better recreate the environment. Although these reconstructions provide clear context of evidence to investigators and jurors to corroborate or disprove testimonies, the nature of these sketches makes them subjective and limited in application.

Laser Scanning

Better suited for large-scale scene reconstructions, terrestrial laser scanners are increasingly used due to their increased range (350 m) compared to other optical techniques (Carew and Errickson 2019; FARO 2019). These scanners operate based upon either continuous frequency modulated (phase-shift) or pulsed (time of flight) techniques to determine distances to objects (Zhang 2013). Many of these systems have internally or externally moving parts to allow data to be captured in 360°, this enables the recording of hundreds of thousands of points per second. However, to cover large environments and reconstruct scenes without shadows the scanner must be moved to capture unseen surfaces. Depending upon the type of system the merging of scans may be done automatically in associated software with or without the aid of markers (FARO 2019). Some device software may also allow for the point cloud information to be exported into CAD software to introduce and manipulate objects as outlined above. However, although these devices are capable of capturing true color environments with fast acquisition and processing time (Buck et al. 2013), these systems can cost in excess of $40,000 limiting their popularity (Carew and Errickson 2019).

Structured Light

In contrast to large-scale laser scanning, structured light is better suited to smaller-scale target objects and surfaces, such as the impact region of a car involved in a road traffic accident. Structured light is the process of projecting a pattern of light onto a target surface and recording the visual deformities caused by that target surface using a camera (Zhang 2013). Due to the nature of structured light, it is best suited for small object/item level modelling, for example, firearms or weapons, as opposed to complete scene recording. However, structured light is capable of recording geometric, morphometric, and color-surface data (Sansoni et al. 2009), and also has fast acquisition and processing times although this is dependent on computational power (McPherron et al. 2009).

Photogrammetry

Having gained significant popularity over recent years, photogrammetry is the practice of obtaining distances and geometric properties from two dimensional (2D) images using single or multiple camera approaches (Hartley and Zisserman 2003). The most common of these approaches used today is Structure from Motion (SfM). SfM is a photo-realistic reconstruction technique that relies upon features being detected and matched across a sequence of images to register camera locations and 3D structure (Lowe 2004; Smith et al. 2016). Recent advancements in digital cameras and

computer vision techniques has made SfM an affordable practical investigation tool without the requirement of specialist professionals (Edelman and Aalders 2018). Additionally, comparative studies by Baier and Rando (2016) have shown that SfM is comparable in accuracy to laser scanning techniques with much shorter recording time and less expense. This is a critical consideration when pressure is there to release a scene. However, extended processing time compared to other techniques was noted in multiple cases (Marcin et al. 2017; Urbanová et al. 2017). In addition to this, the resultant 3D model quality is affected by camera quality and basic knowledge of the user (Edelman and Aalders 2018) as well as the presence of texture within the target environment (Marcin et al. 2017).

State of the Art

Using a range of techniques outlined above as well as others, current state-of-the-art reconstruction methods include the use of Unmanned Aerial Vehicles (UAVs) (see entry ▶ "Drones") equipped with airborne laser scanning systems or cameras for the purpose of SfM. Similar to the methods outlined above, UAVs often use specific designed devices to capture aerial data. Experiments of UAV-based scene recording include on-site body documentation (Urbanová et al. 2017) and road traffic accidents (Pix4D 2019). Having already proven popular in large-scale and outdoor environments both as a tool for orthomosaics and 3D modelling, it is likely that this technology will move indoors. Although the forensic effectiveness of UAV technology within indoor environments is still being established (Bucknell and Bassindale 2017; Parrott et al. 2018).

Despite some of the limitations outlined within these sections, all digital techniques allow for the indefinite digital preservation of an incident scene which allows investigators to revisit the scene at any point once the scene has been released (Edelman and Aalders 2018). With regard to visualizing these results, Koller et al. (2019) propose the use of Virtual Reality (VR) as a useful visualization tool for both training/teaching as well as in the courtroom. 3D modelling is also impacting the courtroom by enabling items to be 3D printed and physically presented to jurors at court (Baier et al. 2018).

Conclusion

To summarize, over recent years our ability to record and reconstruct environments for investigative purposes has advanced dramatically through technological developments, from physical clay modelling and hand-drawn sketches to complete 3D digital reconstructions captured using UAVs and visualized through VR. Largely, reconstruction is beneficial for the investigator to be able to view a scenario in a cohesive manner with all the information available at once, as opposed to flicking through photographs, witness statements, and measurements simultaneously. This overall perspective allows investigators to challenge testimonies and determine the sequence of events more efficiently. A trend that is clear to see from these reconstruction techniques is that as the usability and accuracy of the technology improves, so does the cost, which in most cases is often an overwhelming factor to inhibit progression. Although the value of some of this technology is yet to be fully realized amongst practitioners, as future work emerges on the capabilities and limitations of this technology within a forensic forum, it is likely that many of the technologies outlined earlier will become increasingly common place.

Investigations: Bank Fraud

Sonny Smith
Texas A&M University, College Station, TX, USA

Keywords
Check kiting · Credit card fraud · Forgery · Shoulder surging · Skimming · Social engineering · White collar crime

Definition

Fraud, as an all-encompassing term, is a problem that has negatively affected institutions across the world to the tune of approximately $3.5 trillion per year, with $16.8 billion in US losses (Pascual et al. 2018). In 2014, McAfee and the Center for Strategic and International Studies found the losses from cybercrime alone to be between $375 and $575 billion per year (Insurance Information Institute 2018). Schemes such as identity fraud, credit card fraud, skimming, wire fraud, check tampering, and financial statement fraud have been some of the more common and lucrative methods employed in these schemes. These fraud schemes impact multiple sectors of society, such as government and public service organizations, individuals, financial institutions, online retailers, and traditional brick and mortar merchants.

> *"Data! Data! Data!" he cried impatiently. "I can't make bricks without clay."*
> Sherlock Holmes
> –The Adventure of the Abbey Grange

Introduction

Just as Sherlock Holmes implored Watson, clay, or data (information/clues) in this case, is the key ingredient to making bricks (solving crimes). The more information and clues an investigator can obtain, the stronger the case will be, and the better the chances of catching the perpetrator/s. Depending on the investigation, obtaining the needed data can be as simple as reviewing video footage, collecting fingerprints, or even convincing a suspect to incriminate himself or his group through a thorough interrogation; however, with the advance of technology, obtaining data has become ever more difficult, as criminals have found unique and intricate ways to perpetrate their schemes and hide their steps. These intricate and unique methods of evasion have become more evident in the growing complexity of bank fraud schemes.

Despite these complexities, the general principles of the investigative process remain the same. In essence, the investigator is looking to answer the who, what, when, where, why, and how of the issue at hand. Many times, a number of the variables may already be known, and the investigator must then set out to compile the additional data needed to put the pieces together and complete the rest of the investigative puzzle. In other instances, there are no known facts other than the knowledge that an incident has occurred; thus, the investigator must start with a blank slate in the hopes of determining what has happened and who or what is responsible for it.

The purpose of this entry is to provide an overview of bank fraud and the investigative process. The general topic of bank fraud and investigating bank fraud as an offense is a very complex topic, with many interconnecting criminal elements and schemes, as well as investigative relationships between the public and private sector. Because of these factors and the limited space available for this topic, this entry will provide an overview of these complexities and relationships. The entry will be divided into four (4) sections, with Section I "Introduction and Terms" introducing fraud in general and bank fraud in particular, as well as providing a list of useful definitions. Section II will focus on the "Who" component and will be divided into two subsections: (1) who are the individual(s) committing the crimes and (2) who are groups investigating the crimes. Section III will explore the "What" component; what are some of the more prevalent schemes or crimes being perpetrated? This section will be used to provide examples of the most

prominent bank fraud schemes. Section IV will explore "How" investigators are working together to combat these schemes. The three missing components, *when*, *where*, and *why*, will not be addressed here individually, as they will be addressed indirectly throughout the other sections.

Introduction and Terms

Fraud, as an all-encompassing term, is a problem that has negatively affected institutions across the world to the tune of approximately $3.5 trillion per year, with $16.8 billion in US losses (Pascual et al. 2018). In 2014, McAfee and the Center for Strategic and International Studies found the losses from cybercrime alone to be between $375 and $575 billion per year (Insurance Information Institute 2018). Schemes such as identity fraud, credit card fraud, skimming, wire fraud, check tampering, and financial statement fraud have been some of the more common and lucrative methods employed in these schemes. These fraud schemes impact multiple sectors of society, such as government and public service organizations, individuals, financial institutions, online retailers, and traditional brick and mortar merchants.
